## (57) ABSTRACT

A method and apparatus for shielding a user's private billing data, such as credit card information, or other billing arrangements, but distributing different billing data to businesses during commerce therewith. Also disclosed is assigning the different billing data through real-time and advance distribution of the different billing data to a user, as well. Also disclosed is validating the correctness of a charge through confirmation of the charge with a financial institution, such as a bank, and by comparing itemized charges against expected charges identified by the user.

# CROSS-REFERENCE TO RELATED APPLICATIONS

The present patent application is a divisional of and claims priority from U.S. patent application Ser. No. 09/553,068, filed Apr. 20, 2000, the entire disclosure of which is hereby 10 incorporated by reference as if fully set forth herein.

## BACKGROUND OF THE INVENTION

#### 1. Field of the Invention

The present invention relates to the field of information systems. More specifically, the present invention relates to electronic purchases while maintaining privacy of customer billing data.

#### 2. Background Information

The Internet is a well-known collection of public and private data communication and multimedia networks that operate using common protocols to form a world wide network of networks. Recently there has been an explosion in the availability of "virtual storefronts," e.g., commerce sites, reach- 25 able over the Internet. This rapid growth is due, in part, to the availability of fast, reliable and affordable computing device systems, and the general simplification of networking hardware and configuration. Thus, consumers and businesses alike now have access to hardware that makes effective online 30 commerce commercially practicable.

To conduct online transactions, a business typically sets up a home page (e.g., "web site") on the World Wide Web, which is a logical overlay of the Internet. Web sites are simply machines located someplace within the Internet, with tradi- 35 tional naming conventions for the machines, e.g., named WWW, and holding themselves available to interact using standard protocols such as Hypertext Transfer Protocol (HTTP), and programming languages or environments such as Hypertext Transfer Protocol HTML, XML, Java, JavaS- 40 cript, Java Beans, ActiveX, Visual Basic, or the like.

To make a purchase via a web site, a customer executes a "browser," such as the Internet Explorer, Netscape Navigator, or other network aware application program that is configured to communicate with a business' web site. The customer 45 locates a particular product, and proceeds to a "check out" web page (or equivalent) to process a purchase transaction. At this point, the customer must enter credit card data and other data sufficient to identify the customer and allow purchase of goods to occur.

Historically, thieves have attempted to monitor such online transactions so as to steal consumer data to allow engaging in subsequent fraudulent transactions. Such monitoring is possible due to the inherently insecure nature of the Internet communication protocol. Internet communication follows 55 the Transmission Control Protocol/Internet Protocol (TCP/ IP), where data is broken into small packets that are individually sent to a recipient, received by the recipient and then re-assembled into the original data.

Unfortunately, anyone with access to a network has the 60 ability to "snoop" network traffic on that network. Thus, anyone capable of monitoring some portion of the communication path between the customer and business is then able to monitor the purchase transaction. To overcome this security problem, various protocols, e.g., IP Security (IPSEC), Secure 65 Sockets Layer (SSL), Secure HTTP (S-HTTP) have emerged to allow a business and a customer to securely communicate.

Although the data packets can still be snooped, their contents are now encrypted and unusable. Thus, thieves have recently begun to attack, or "hack," the online commerce sites so as to steal consumer data stored within databases maintained by the business. Since private consumer data, such as credit card information, once received by a business, is reassembled and decrypted by the business, the data is available for theft.

Thus, what is needed is an environment which provides consumers with the ability to engage in online transactions in a more secure manner.

# SUMMARY

Apparatuses and methods registering a user with multiple businesses, where each business is given billing data, such as credit card data, that is unique to that business. Apparatuses, such as computing devices, and consumer electronic devices such as a telephone, communicate with a billing service so that billing data can be generated for particular businesses and used in commercial transactions with the business. Such communication and generation may be in advance of a purchase, or generated in real-time during a purchase.

# BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates a client in communication with a network. FIG. 2 is a flow chart according to one embodiment of the invention, illustrating a client registering with a business for purchasing a good.

FIG. 3 is a flowchart according to one embodiment of the invention, in which a client purchases a good using billing data provided in advance by a billing service.

FIG. 4 is a flowchart according to one embodiment of the invention, in which a client purchases a good using billing data provided in real-time by a billing service.

FIG. 5 illustrates one embodiment of a suitable computing environment in which certain aspects of the illustrated invention may be implemented.

# DETAILED DESCRIPTION

In various embodiments of the invention, a customer is able to establish accounts with web sites without revealing private billing information such as credit card numbers, advance debit arrangements, invoice arrangements, etc. to a web site/ business from whom the customer purchases goods.

FIG. 1 illustrates a client 100 in communication with a 50 network 104. Also attached to the network are multiple servers 102 (business web sites), such as those provided by e-commerce sites, online retailers, or other businesses seeking to engage in commerce with by way of networked cus-

It is assumed the client comprises a computing device, such as a personal computer, which operates on behalf of a user (the purchaser of the good). In alternate embodiments, the client may be incorporated into an electronic card, a telephone (FIG. 6), a personal digital assistant (PDA), a portable audio device, a portable audiovisual device, a cellular telephone, a key-chain dongle, or within an automobile or other transportation device.

It is further assumed that each of the network locations to which a client may communicate provide a "web site" for engaging in commercial transactions, and will collectively be referred to as "businesses." For the purposes of this description, the phrase "web site" is intended to be a general refer-

# US 7,664,701 B2

ence to a network "presence" maintained by a business as well a logical presence maintained on behalf of a business.

The clients 100 and businesses 102 are in communication. through the network 104, with a billing service 106. The billing service is configured to allow clients 100 to reduce the 5 risk of disclosing billing data, such as personal credit card numbers, debit card numbers, bank account numbers, and the like, to businesses 102. In one embodiment, the billing service facilitates commercial transactions by generating substitute billing data that the client 100 can use when engaging in 10 commercial transactions with businesses 102. The phrase "substitute billing data" refers to valid billing data that is owned and/or controlled by the billing service 106, where billing data is temporarily or permanently distributed to clients 100 to replace personal and/or private billing data of the 15

Also in communication with the client 100 and businesses 102 by way of the network 104, is an encryption server 108. The encryption server can be used to provide encryption keys to a client 100 and business 102 to allow them to engage in secure communications. In one embodiment, the encryption server 108 is used to engage in conventional public key encryption systems, where the encryption server provides directory assistance services, allowing clients 100 and businesses 102 to retrieve public encryption keys.

In one embodiment, public key encryption services are used in addition to encryption services already available to a client (e.g., such as those available within a web browser or other communication program used by the client 100). In an alternate embodiment, already available encryption services, such as those provided by a web browser, are used to securely communicate with the encryption server 108 to obtain encryption keys for opening a secure communication channel between the client 100 and business 102.

This allows weaker security afforded by the client communication environment, e.g., a 40 bit or other short key system. to be used to communicate with the encryption server 108 to obtain more secure (e.g., longer) encryption keys. In this alternate embodiment, the built in security can also be used to transfer non-public key based cryptosystem keys, such as single use session keys, to the client 100 and business 102 for engaging in commerce.

Associated with clients 100 are local storage, such as a database 110, that can store billing data and encryption data for use during transactions with a business 102. In one embodiment, records 112 within the database 110 are keyed on a business 102 identity reference. A business identity can be tracked by way of business name, unique identifier for the business (e.g., a tax ID or other assigned/selected identifier), 50 uniform resource locator (URL), TCP/IP "dot quad" network address (e.g., 10.1.2.3) used to access the business 102 over the network 104, or a combination of these and/or other references.

As illustrated, the client local storage containing the data- 55 base 110 is integral to a client 100, such as within local mass storage device(s). However, it will be appreciated that the database may be contained within a separate computing device (not shown) associated with the client 100, or maintained by or in conjunction with the billing service 106 or 60 encryption server 108. For example, the billing service 106 or encryption server 108 may be used to store backup copies of billing data.

FIG. 2 is a flow chart according to one embodiment of the invention, illustrating a client 100 registering with a business 65 102 for purchasing a good (e.g., a physical or electronic item) from the business.

The first illustrated operation is the user initializing 200 the computing device. It is assumed that initialization includes all steps required to boot, wake from an idle state, or otherwise start the computing device and configure it for purchasing activity. Assume that the computing device is a handheld "palmtop") personal computer executing the Microsoft Windows operating system. After initialization, the user loads 202 a communication program through which to engage in the purchasing activity.

It will be appreciated that a number of environments may be used to implement the communication program. For example, a dedicated/custom application program may be designed to access businesses over a network. Alternatively, the communication program can be built using communication features provided by Internet web browser products, such as Microsoft Internet Explorer, Netscape Navigator, or Opera.

In this latter environment, the communication program may be implemented in one of, or a combination of, Java, JavaScript, JavaBeans, ActiveX, Visual Basic, HTML, DHTML, or other Internet related programming environments. It is assumed herein the communication program is based on an Internet browser, and that traditional Internet related communication protocols (e.g., TCP/IP, HTML, etc.) are used to communicate with businesses over the Internet. As discussed with respect to FIG. 1, each business provides a web address to which a client can connect to engage in purchase transactions.

After communication program initialization, the computing device is used to register 204 the user with a first web site maintained by a first business. Note, however, that even though the illustrated embodiment requires registration, it will be appreciated that in other embodiments, such registration need not occur first, or at all. To register, the computing device contacts 206 the first web site. In response the web site sends an acknowledgement 208. Since an Internet browser is assumed in use, the contact is by way of directing the browser to an appropriate receiving port monitored by a web server of the first business. It is assumed that port 80, the traditional Internet communication port, is used for communication. In the web browser context, acknowledgement can be determined by receiving a "home page" or start page from the first business' web server.

If 210 no acknowledgement is received, then a registration error has occurred and processing of this registration halts 212; in one embodiment, processing continues on (not shown) with registration attempts with other businesses. If acknowledgement is received, then the client 100 tells the business 102 it is interested in registering with the business

In one embodiment, the registration process is automated, where the business web server is configured to receive a registration command from the client, and in response the business web server sends the client registration forms to complete. For example, in response to the registration command, an HTML form (or equivalent structure) containing fields for the user's name, address, telephone number, and billing data, such as credit or debit card numbers, invoicing preferences, etc., is sent 214 to the client. This form (or equivalent structure) is completed 216 and returned 218 to the business. In response, the business 102 processes the returned data and registers 220 the client with the billing data returned 218 to the business web server.

Completion of the form can be automated, through automated parsing of the form to identify various fields to fill out. In one embodiment, the extensible markup language (XML) is used to encode forms with semantic meaning to facilitate

automatic interpreting and completing of a form. In an alternate embodiment, the user is allowed to review and complete a form with data known to the user, or the user can be provided with an opportunity to review and change a form completed by the computing device. In another embodiment, a special 5 communication port, analogous to browser port 80, is used to send and receive registration data.

It will be appreciated that even though the above description assumes registration of a user with businesses, such registration is not required in order to obtain billing data to 10 present to such businesses.

FIG. 3 is a flowchart according to one embodiment of the invention, in which a client 100 purchases a good using billing data provided in advance by a billing service 106. This figure concerns the logical data flow for obtaining billing data 15 used by a client 100 in purchasing a good from a business 102.

As discussed above, there are intrinsic security issues within networks, such as the Internet or home/office local area networks (LANs), when more than just the parties to a conversation may "snoop" data passing on the network so as to 20 discover secrets (e.g., credit card data or other sensitive data) disclosed during the conversation. In addition to attempts to securely encrypt the data transfers themselves, as will be discussed below, client provided billing data can be customized so as to reduce risk of theft and/or fraudulent use.

A first operation is to contact 302 the billing service. In response, the billing service asks 304 for the business 102 with which the customer seeks to interact. As discussed above, a variety of different information can be provided to identify the business. For simplicity, it is assumed that the 30 business name is used to identify the business 102. The business name is provided 306 to the billing service 106. In response the billing service generates 308 billing data that can be used by the client in future transactions between the client and the identified business. The correspondence between bill- 35 ing data and business is tracked by the client 100 and/or it is tracked by the billing service 106.

Once the billing data is known, the client 100 can then contact 310 a business and decide 312 on a good to purchase. In response to a purchase decision, the business sends 314 a 40 payment request to the client to arrange for receiving payment for the good, However, unbeknownst to the business 102, in response to the payment request, instead of sending personal credit card information, or other payment data, the client 100 instead sends 316 the business the billing data created in 45 advance by the billing service for the business 102.

In one embodiment, the billing service obtains the billing data to distribute to clients by entering into agreements with banking institutions (or equivalent). The billing service is provided a large number different billing data, e.g., credit 50 card numbers, debit card numbers, etc., and the billing service may also set up internal invoice accounts and the like. These different billing data are provided to a client 100 when the client registers with the billing service the client's intent to purchase from a business 102.

In one embodiment, billing data presented to a client 100 is uniquely associated with the particular business 102 the client 100 intends to purchase from. Charges made against the billing data are received 318 by the billing service in due course through standard financial institutions such as banks, savings 60 and loans, investment houses, and the like. These charges are verified 320 for validity.

In one embodiment, the client informs the billing service of the items purchased (or possibly just item categories) so that the billing service may audit a particular charge to ensure only 65 expected purchases appear on the charge. In one embodiment, the client informs the billing service of billing data that is

provided to businesses so as to facilitate verification, For example, the origin of a charge can be compared against the business associated with the billing data.

In this embodiment, if 322 the charge origin fails to match the business expected to be making the charge, then the charge may be fraudulent. Consequently, the charge is contested 324 so as to allow the client to investigate the validity of the charge before being billed for the charge. However, if 322 the expected business matches the charge origin, then the client is billed for the purchase amount paid by the billing service. Note that the client may be billed in a manner entirely different from the payment system required/used by the business 102.

For example, the client may have arranged to have purchases automatically deducted from a bank account, while the billing service 106 is responsible for honoring a charge made by the business against credit card data provided by the client 100. Alternatively, the client may have arranged payment such that the billing service performs a direct wire transfer from a client's bank account directly into a receivables account of the business 102.

By associating a particular business with billing data, it is possible to account for a thief stealing apparently valid billing data from a business' Internet web server, and then attempting to engage in fraudulent activity. In addition to contesting 324 improper charges, the billing service can be configured to retire billing data that has been compromised.

FIG. 4 is a flowchart according to one embodiment of the invention, in which a client 100 purchases a good using billing data provided in real-time by a billing service 106. It will be appreciated that even though FIGS. 3 and 4 are presented separately, a single client may use both real-time generated billing data, and advance-obtained billing data, depending on the business.

After contacting 400 a business 102 from which a purchase is to be made, the client 100 user decides 402 on the purchase; this decision is transmitted to the business. It will be appreciated that this decision-making process may include the user reviewing various offerings of the business 102 (e.g., "surfing" the business web site), as well as directly connecting to a particular uniform resource location (URL) for purchasing a product (a purchase link may be known in advance).

In response to the purchase decision, the business 102 sends 404 a payment request to the client. In response, analogous to that described above for FIG. 3, the client contacts 302 the billing service 106, provides 306 the business name to the service, and receives in real time billing data generated 308 by the billing service for the business 102. In one embodiment, the billing data presented to the client 100 is uniquely associated with the particular business 102 the client 100 is purchasing from.

As with FIG. 3, unbeknownst to the business 102, in response to the payment request 404, instead of sending personal billing information of the user, the real time generated billing data is instead sent 406 to the business.

Charges made against the billing data are received 408 by the billing service. As with FIG. 3, these charges are verified 410 for validity. If 412 the charges appear invalid/fraudulent, the charge may be automatically contested 324 or other action taken, such as highlighting the transaction to the user to allow review of the validity of the charge.

If 412 the charge is valid, then the client is hilled for the purchase amount paid by the billing service. Note that the client may be billed in a manner entirely different from the payment system required/used by the business 102. In one embodiment, highlighting occurs within the bill sent to the user to accentuate invalid or possibly invalid charges. High-

# US 7,664,701 B2

lighting can be by a variety of different methods, such as printing an offending charge in a bold typeface, in a larger type size, in a different font from the rest of the bill, in a different color, in a different section of a bill which organizes suspect charges in a single region, or through a combination 5 of these or other highlighting techniques.

In one embodiment, the billing service 106 tracks expiration dates for charges made by the user. That is, if a charge is received against a credit card number provided to a client 100 for purchasing from a business 102, there may be a timeout 10 period, such as 60 days, in which a charge must be contested if such charge is to be ever contested. In such circumstances, the highlighting may include prioritization of listed charges according to expiration of contest periods. In another embodiment, a separate bill section is provided for contestable 15 charges expiring within a certain amount of time, such as two

In one embodiment, the client can elect to be billed electronically, in addition to or in lieu of receiving a physical bill printed on paper. Electronic billing can be by way of E-mail- 20 ing or otherwise electronically transferring bill data to the client. Alternatively, bills can be maintained by the billing service 106, such as through personalized web pages to which a client can log in and review charges. In one embodiment, the personalize web pages include buttons or other controls to 25 allow disputing charges. In one embodiment, single-click buttons are provided with listed charges, where a single click of the button institutes a dispute process to cause the selected charge to be reviewed for fraud.

FIG. 5 and the following discussion are intended to provide 30 a brief, general description of a suitable computing environment in which certain aspects of the illustrated invention may be implemented. The invention may be described by reference to different high-level program modules and/or lowlevel hardware contexts. Those skilled in the art will realize 35 that program module references can be interchanged with low-level hardware instructions.

Program modules include procedures, functions, programs, components, data structures, and the like, that perform particular tasks or implement particular abstract data types. 40 The modules may be incorporated into single and multiprocessor computing systems, as well as hand-held devices and controllable consumer devices (e.g., Personal Digital Assistants (PDAs), cellular telephones, set-top boxes, Internet appliances, etc.). It is understood that modules may be 45 implemented on a single computing device, or processed over a distributed network environment, where modules can be located in both local and remote memory storage devices.

An exemplary system for implementing the invention includes a computing device 502 having system bus 504 for 50 coupling together various components within the computing device. The system 504 bus may be any of several types of bus structures, such as PCI, AGP, VESA, Microchannel, ISA and EISA, etc. Typically, attached to the bus 504 are processors 506 such as Intel, DEC Alpha, PowerPC, programmable gate 55 arrays, etc., a memory 508 (e.g., RAM, ROM), storage devices 510, a video interface 512, and input/output interface

The storage systems and associated computer-readable media provide storage of data and executable instructions for 60 the computing device 502. Storage options include harddrives, floppy-disks, optical storage, magnetic cassettes, tapes, flash memory cards, memory sticks, digital video disks, and the like, and may be connected to the bus 504 by way of an interface 526.

Computing device 502 is expected to operate in a networked environment using logical connections to one or more

remote computing devices 516, 518 through a network interface 520, modem 522, or other communication pathway. Computing devices may be interconnected by way of a network 524 such as a local intranet or the Internet. Thus, for example, with respect to the illustrated embodiments, assuming computing device 502 is a client seeking to purchase goods, then remote devices 516, 518 may be a billing service 516 providing substitute billing data to the user for purchasing goods from a business 518.

It will be appreciated that remote computing devices 516, 518 may be configured like computing device 502, and therefore include many or all of the elements discussed for computing device 502. It should also be appreciated that computing devices 502, 516, 518 may be embodied within a single device, or separate communicatively-coupled components, and include routers, bridges, peer devices, web servers, and application programs utilizing network application protocols such as HTTP, File Transfer Protocol (FTP), Gopher, Wide Area Information Server (WAIS), and the like.

Having described and illustrated the principles of the invention with reference to illustrated embodiments, it will be recognized that the illustrated embodiments can be modified in arrangement and detail without departing from such principles.

And, even though the foregoing discussion has focused on particular embodiments, it is understood that other configurations are contemplated. In particular, even though expressions such as "in one embodiment," "in another embodiment," and the like are used herein, these phrases are meant to generally reference embodiment possibilities, and are not intended to limit the invention to particular embodiment con-

As used herein, these terms may reference the same or different embodiments, and unless expressly indicated otherwise, are combinable into other embodiments. Consequently, in view of the wide variety of permutations to the abovedescribed embodiments, the detailed description is intended to be illustrative only, and should not be taken as limiting the scope of the invention. What is claimed as the invention, therefore, is all such modifications as may come within the scope and spirit of the following claims and equivalents thereto.

What is claimed is:

- 1. A method for a user to provide substitute billing data in lieu of personal billing data, comprising:
  - an electronic device facilitating a request to a billing service for first and second distinct credit card numbers, including identifying each business with which the first and second distinct credit card numbers are to be used;
  - the electronic device obtaining the first and second distinct credit card numbers from the billing service for use by the user as a substitute for said personal billing data, the first and second distinct credit card numbers associated with each said business by the billing service;
  - the electronic device facilitating one or more purchasing transactions with a first associated business using the first credit card number; and
  - the electronic device facilitating one or more purchasing transactions with a second associated business using the second credit card number.
- 2. The method of claim 1, wherein the electronic device is a portable digital assistant, said method further comprising: the electronic device disposing said distinct credit card numbers in a memory within the electronic device;
  - the electronic device identifying a connection to, or a submitted request to connect to, a particular business;

# US 7,664,701 B2

- the electronic device determining whether a selected credit card number associated with the particular business is present in the memory; and
- if found in the memory, the electronic device displaying the selected credit card number for the particular business. 5
- 3. The method of claim 2, further comprising:
- if no selected credit card number for the particular business is found, the electronic device then selecting a third credit card number from said distinct credit card numticular business; and
- the electronic device automatically conveying to the billing service of said selection of said third credit card number to conduct purchasing transactions with the particular
- 4. The method of claim 1, wherein the method further comprises:
  - the electronic device notifying the billing service of said selection of said first and second distinct credit card numbers to facilitate purchasing transactions with said 20 first and second businesses respectively, including identifying the first and second businesses for which the first and second distinct credit card numbers were selected.
  - 5. A method comprising:
  - a billing service registering a user;
  - the billing service receiving identification of a first and a second business with which the user intends to conduct one or more purchasing transactions;
  - the billing service associating a first and a second billing data, that are separate and distinct, with the first and the 30 second business respectively; and
- the billing service providing the first and second billing data for use by the user as substitutes for personal billing data for subsequent purchasing transactions
- 6. The method of claim 5, wherein said first billing data 35 further comprises:
  - a third billing data for use by said first business for charging the billing service for goods purchased by said user; and
  - a fourth billing data for use by the billing service for billing the user for charges received from said first business.
  - 7. The method of claim 5, further comprising:
  - the billing service providing in real time said first and second billing data to an electronic device used by the
- wherein the electronic device is operable to purchase goods 45 from said first and second businesses.
- The method of claim 5, further comprising:
- the billing service receiving notification of usage of said first and second billing data with said first and second businesses from an electronic device used by the user.
- 9. The method of claim 8, wherein said receiving notification comprises receiving a charge against one of said first and second billing data by a corresponding one of said first and second businesses.
  - 10. An apparatus comprising:
  - a storage medium having stored therein a plurality of programming instructions designed to enable the apparatus, when the programming instructions are executed, to register a user, receive identification of a first and a second business with which the user intends to conduct one or more purchasing transactions, associate a first and a 60 second billing data, that are separate and distinct, with the first and the second business respectively, and provide the first and second billing data for use by the user as substitutes for personal billing data when conducting purchasing transactions with the first and the second businesses; and

10

- a processor coupled to the storage medium to execute the plurality of programming instructions.
- 11. The apparatus of claim 10, wherein said first billing data further comprises:
- a third billing data used by said first business for charging the billing service for goods purchased by said user; and a fourth billing data for use by the billing service for billing
- the user for charges received from said first business. 12. The apparatus of claim 10, wherein the programming bers to facilitate purchasing transactions with the par- 10 instructions, when executed by said processor, enable the apparatus to:
  - provide in real time said first billing data to an electronic device operable to purchase goods from said first busi-
  - 13. The apparatus of claim 10, wherein the programming 15 instructions, when executed by said processor, enable the apparatus to:
    - receive notification of usage of said first billing data with said first business from an electronic device used by a purchaser.
    - 14. The apparatus of claim 13, wherein said receiving notification comprises receiving a charge against said first billing data, the charge being made by said first business.
    - 15. An apparatus for a user to provide substitute billing data in lieu of personal billing data, comprising:
    - means for facilitating a request to a billing service for first and second distinct credit card numbers;
    - means for identifying each business with which the first and second distinct credit card numbers are to be used;
    - means for obtaining from the billing service the first and second distinct credit card numbers associated with each business for use by the user as a substitute for said personal billing data;
    - means for facilitating one or more purchasing transactions with a first associated business using the first credit card number; and
    - means for facilitating one or more purchasing transactions with a second associated business using the second credit card number.
    - 16. The apparatus of claim 15, further comprising means for notifying the billing service of said selection of said first and second distinct credit card numbers to facilitate purchasing transactions with said first and second businesses respectively, and means for identifying the first and second businesses for which the first and second distinct credit card numbers were selected.
    - An article of manufacture including a computer-readable medium having instructions stored thereon that, if executed by a computing device, cause the computing device to perform a method comprising:
    - registering a user:
    - receiving identification of a first and a second business with which the user intends to conduct one or more purchasing transactions;
    - associating a first and a second billing data, that are separate and distinct, with the first and the second business respectively; and
    - providing the first and second billing data for use by the user as substitutes for personal billing data when conducting purchasing transactions with the first and the second businesses.
    - 18. The article of manufacture of claim 17, wherein the instructions, if executed by the computing device, further cause the computing device to receive notification of usage of said first billing data with said first business from an electronic device used by a purchaser.

# (57) ABSTRACT

An Internet interface provided by an internet web server provides web pages presents in a manner which is tailored to an individual user. The interface provides web site navigation data to the user in accordance with personal preferences provided by the user. A site map program function then provides web site navigation data to the user, in order to provide a display depicting portions of the web site visited by the user.

# CROSS REFERENCE TO RELATED APPLICATION(S)

This application is a continuation of U.S. patent application Ser. No. 09/318,917, U.S. Pat. No. 6,816,849, filed May 26, 1999, which in turn claims priority from U.S. provisional 10 application No. 60/086,671 filed May 26, 1998, which are incorporated by reference as if fully set forth,

## FIELD OF INVENTION

This invention pertains to the global computing network otherwise known as the Internet or the World Wide Web, More particularly, the invention pertains to a system for selectively tailoring information delivered to an Internet user depending upon the particular needs of the user.

## BACKGROUND

The Internet is a global computer network that is rapidly changing the landscape of the business community and has of the global community. By its very nature, the Internet provides a flexible vehicle to deliver information from any point on the globe to any other point on the globe. Providing such a vast amount of information on demand is a feat which is unparalleled in history in both size and scope. However, due 30 to the limitations inherent with computer hardware, modems and telephonic systems, only a small portion of the capabilitics of the Internet are utilized today. As the performance of computer hardware and software catches up with the expectations of the Internet-using community, the applications for 35 which the Internet is used will increase tremendously.

Use of the Internet is in its infancy. Much to the chagrin of the Internet-using community, the press constantly features articles and commentary on the Internet which is overly simplistic and misleading. Much of the capabilities of the Internet 40 remain more hype than fact. Since evolution of the Internet is in its rudimentary stages, no one can predict where the fron-

One of the current problems with the Internet is that inexperienced people in the business community and the user 45 community tend to view the Internet as a natural extension (or slight modification) of the currently existing media. For example, much of the public uses the Internet as a high tech phone book whereby a user can obtain detailed information regarding a company's products, services or other back- 50 ground information regarding a company. A perusal of home pages currently existing on the World Wide Web confirms that home pages are currently a hybrid of the business-to-business Yellow Pages® directory and a television commercial. The home pages are unable to obtain any information regarding 55 the specific Internet users which are contacting the home page nor are they able to deliver information tailored specifically to that user without the user experiencing a tedious "virtual gauntlet" of boring questions that they must answer time and time again for each home page that is accessed. The initial 60 enthusiasm and mystique associated with the Internet will quickly evaporate unless Internet users and the business community begin to utilize the Internet to its fullest potential.

Accordingly, there exists a serious need for delivering useful information to an Internet user that can be depended upon 65 to deliver quality data as reliably as current utilities are deliv-

# SUMMARY

The present invention is a system for delivering information from an information provider to an information user that is selectively tailored toward the capabilities of the information provider and the needs of the information user. The system includes an interactive interface which provides a medium for information users to communicate with information providers. More specifically, the system includes means for the information user to tailor the profile of the information user depending upon the needs or desires of the information user. Separate means permit the information provider to view the information user profile and to structure the information seen by the information user in a format that is most suitable to that information user.

The system also enables the information user to operatively tailor their profile on a real time basis. Thus, the information provider may tailor the information provided to the Internet using community depending upon the time of day, business 20 conditions or other factors.

Accordingly, it is an object of the present invention to provide an advanced Internet interface between Internet information users and Internet information providers.

Other objects and advantages will become apparent to begun change the way people perceive themselves as citizens 25 those skilled in the art after reading the detailed description of a presently preferred embodiment.

#### BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of the interface between information users and information providers over the Internet according to the prior art.

FIG. 2 is a block diagram of the web page structures according to the prior art.

FIG. 3 is a block diagram of the interface between information users and information providers over the Internet according to the present invention.

FIGS. 4A-4C are database structures of user information. FIG. 5A is a block diagram of information provider according to the present invention.

FIG. 5B is a file structure of information identifiers according to the present invention.

FIGS. 6A and 6B are illustrations of web pages according to the present invention.

FIG. 7 is an illustration of a web page structure according to the present invention.

# DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT(S)

The preferred embodiment will be described with reference to the drawing figures wherein like numerals represent like elements throughout.

A block diagram of the interface between current information users and information providers over the Internet is shown in FIG. 1. The information transport infrastructure 10 includes all of the infrastructure 10 required to convey information between the plurality of information providers 20, 22, 24, 26 and plurality of information users 12, 14, 16, 18. This transport infrastructure 10 includes, but is not limited to, a wireless or wired public or private telephone system, a local area network (LAN) or a wide area network (WAN) upon which the information users 12, 14, 16, 18 or information providers 20, 22, 24, 26 are resident, the plurality of way stations in between, and all of the computing resources required to deliver the information. It should be recognized that this infrastructure 10 could include the local cable tele-

vision (CATV) infrastructure, telephone company infrastructure or even the wires provided by the electric company over which information may be transmitted. It should also be recognized that the information may be transmitted by satellite or microwave means and the present example should not 5 be viewed as a specific limitation upon the scope of the present invention.

As shown in FIG. 1, as each information user 12, 14, 16, 18 utilizes the Internet to access one or more information providers 20, 22, 24, 26, each information provider 20, 22, 24, 10 26, such as a Web page, will appear identical to each information user 12, 14, 16, 18. There is no tailoring of information to each information user 12, 14, 16, 18. Of course, an information user 12, 14, 16, 18 can run the aforementioned "virtual gauntlet" of questions to obtain the information they 15 require, but this process is extremely frustrating and time consuming. Additionally, much of the information requested from the information user 12, 14, 16, 18 by an information provider 20, 22, 24, 26 is standard information such as an information user's name, address and other personal or finan- 20 cial information.

Most Web pages are structured as a logical tree and branch format as shown in FIG. 2. First, the information user 12, 14, 16, 18 accesses the desired home page 40. As the information user 12, 14, 16, 18 inputs information and makes selections, 25 the information user 12, 14, 16, 18 gains access to additional tiers of information. For example, if the first choice 42 is selected by information user 12, 14, 16, 18 on the home page 40, the information user 12, 14, 16, 18 will be shown a second tier of choices 50, 52, 54. Selection of the first choice 50 from 30 this second tier of choices 50, 52, 54 will provide access to a third tier of information with three additional choices 56, 58, 60. In this manner, the Web page 40 will provide incremental additional information in response to the selections made by the information user 12, 14, 16, 18. Ultimately, the information user 12, 14, 16, 18 will acquire the information they need after one or more attempts or they will give up in frustration and access a competitor's home page or make a telephone call directly to the company.

The system 9 of the present invention for providing an 40 advanced, selectively tailored Internet interface is shown in FIG. 3. As shown, both the information users 12, 14, 16, 18 and the information providers 20, 22, 24, 26 are selectable and changeable entities; in contrast to the static entities that presently comprise the Internet. As shown, the information 45 user 12, 14, 16, 18 may tailor their information user profile as needed to acquire specific information. In this manner, one might even view the information user 12, 14, 16, 18 as having "multiple personalities."

As shown in FIG. 4A, for example, the information user 12, 50 14, 16, 18 may have a business profile 200 which is specifically tailored toward the information user's 12, 14, 16, 18 business needs. The profile 200 comprises a file 202 having a plurality of fields 204 which hold data that the information user 12, 14, 16, 18 is male, Caucasian, fiscally conservative, 55 politically conservative, is employed by a Fortune 500 company, is employed in a sales position, has an undergraduate degree in economics, speaks English and is a U.S. resident.

Alternatively, as shown in FIG. 4B, the information user's 12, 14, 16, 18 profile 220 for accessing the Internet for plea- 60 sure comprises a file 202 having a plurality of fields 204 which hold data that the information user 12, 14, 16, 18 is a male, Caucasian, college graduate, has a liberal arts degree, homosexual, speaks several languages, has an annual income of \$70,000-\$100,000 socially liberal and fiscally liberal. It 65 should be noted that a data file 250 having a standard format as shown in FIG. 4C may be adopted by all information users

12, 14, 16, 18 and information providers 20, 22, 24, 26 on the Internet. In this manner, a user may simply check or fill-in any of those user profile attributes 252A-252N that are applicable. As shown, there are almost an unlimited number of columns which may be created to identify all of a user's attributes 252. Additionally, a plurality of profiles 260A-260N may be created by the user. For example, the user may create a business profile 260A for all of his or her business trades, and then create several personal profiles 260B, 260C for their personal traits. This profile is stored in computer memory (not shown) and transferred to an information provider 20, 22, 24, 26 when a Web page is accessed. These multiple profiles 252A-252N are not unlike the multiple personalities that currently exist in every day life for many individuals. In accordance with the teachings of the present invention, the profiles 252A-252N are selectively tailored to the needs of the information user 12, 14, 16, 18 at a particular time. Although several current Web pages permit a user to create a profile for that particular Web page, the information user 12, 14, 16, 18 must create this rudimentary profile each time they access the Web page. The present invention has the advantage that a detailed standard profile 252 may be created having an tremendous amount of detail and selectivity then this profile 252 may be utilized with any information provider that accepts the stan-

Referring to FIG. 5A, an information provider 300 in accordance with the present invention is shown. The information provider 300 is a virtual panoply of information which is placed in a mosaic most pleasing to the information users 12, 14, 16, 18. The information on the Web page 302 may be thought of as a mosaic of electronic tiles A, B, C1-C16, D, E, F, G each of which have a portion of the Web page 302. Each tile A-G is a result of a separate data stream 310-322 which individually updates the tiles A-G. The tiles A-G may change, and the format and location of the data streams A-G may change as a result of the change in the data streams. As shown, the tiles A-G may be changed on a yearly, quarterly, daily, hourly or constant basis. Additionally, as shown, the entire Web page 302 may be changed, or only one or more portions of the Web page 302 may be changed as will be explained in detail hereinafter.

Each data stream 310-322 has a set of information identifiers for identifying the type of information provided by the data stream 310-322. For example, the data stream 310 which supplies section A may carry general information regarding the Web page's owner such as a corporation. The file structure of the information identifiers 340A-340N is shown in FIG. 5B. Among the plurality of other data streams 312-324 may exist intellectual property information such as a company's copyright and trademark notifications (section G) 318; directions on how to reach the corporation's headquarters (section F) 320, sales or service locations (section E) 322; and a plurality of other information related to a company's products or services (sections B, C, D and H) 323, 314, 324, 312. It should be apparent even to those with rudimentary skills in the art that the foregoing discussion regarding the data streams 310-324 involving a company's products or services may apply equally to any of the other data streams that are set forth on a Web page 300.

The tailoring of a company's information or services will now be explained in detail hereinafter. The three data streams that will be selected are a company's logo (section H) 312, a company's product line (section D) 324 and the description of the product line (section B) 323. Although some of the data streams may be individually linked, such as a product and the

description of the product and the price of the product; they will be treated separately for simplification of the explana-

Tailoring of the data stream 312 of the company's logo will now be described. As shown in FIG. 6, this or any other data 5 stream 310-324 may be tailored toward the time of day. This will give the information user 12, 14, 16, 18 the pleasing experience that the Web page 302 is "fresh." For example as shown in FIG. 6A, the logo H may be profiled by a rising sun during the early morning hours, a bright sun during the day and a setting sun in the late afternoon and early evening hours. The moon and stars may come out after nightfall, as shown in FIG. 6B, and would be an indication of the actual time of day. Although this may appear as a gimmick, the information user 12, 14, 16, 18 may access the Web page 302 all day long without actually seeing the same Web page 302 twice. It should be recognized that other portions of the Web page 302 may be likewise tailored. This could also be a powerful marketing concept whereby the logo might change color for a certain period of time indicating that the company's products are on sale, the stock is doing well or that the company is 20 hiring. Any aspect of the logo H may be changed to provide useful information to the information user 12, 14, 16, 18. Additionally depending upon the profile 252 of the information the users 12, 14, 16, 18, a Japanese resident accessing a Web page may view a "sun rising" page, while simulta- 25 neously a U.S. resident will see the moon, stars and nightcap. The profile 252 will be downloaded to the information provider 20, 22, 24, 26.

Referring back to FIG. 5A, the data stream 323 concerning a company's products B will now be described in detail 30 hereinafter. This data stream 323 is shown in greater detail in FIG. 7. As shown, the data stream 323 may comprise a plurality of separate data streams 323A-323C which change on a basis set by the information provider 20, 22, 24, 26. The first data stream 323A, for example, pertains to a company's "high end" line of products 380, the second data stream 323B may comprise a company's "middle end" line of products 382, and the third data stream 323C may comprise the company's "low end" line of products 384.

Each particular data stream 323A-323C may comprise the same products throughout the day as shown in FIG. 7, or may change periodically throughout the day, or based upon the time of day. For example, the high end line of products 380 may relate to gourmet coffee; the middle end line of products may relate to your average "cup of joe" 382; and the third data stream 323C may relate to your "get it hot" coffee line for 45 people who are looking only for a caffeine intake and are willing to "choke down" any sludge 384. These three lines of products 380-384 may be displayed until approximately 11:00 a.m. Thereaster, three new high, middle and low end lines of products 380-384 are described such as a company's 50 soda or tea beverage line. In the evening, the three data streams 323A-323C may again change to liquors used for after dinner drinks.

Referring to the high end product description data stream 323A, this data stream 323A may be selectively tailored in a 55 different manner as will be described in detail hereinafter. For example, the data stream 323A may actually comprise three separate lines of data 323A1, 323A2, 323A3, one tailored towards very conservative, serious or older individuals 323A1, one tailored towards "no frills" type people who seek only raw data regarding a product, such as health conscious  $^{60}$ individuals 323A2; and a third data stream that is playful, light and funny for the common Internet surfer 323A3. Accordingly, going along with the present example the high end line of coffee products may be described in the conservative data stream as "a succulent blend of Columbian and 65 Arabica beans which are blended for an exquisite taste and are dry roasted to relieve the coffee of any bitterness." This type

of explanation is specifically tailored to "high income and high end serious and conservative individuals who are looking for a premium product." The description of the high end product for the "data seeking" type of individual may read as follows "a blend of 60% Arabica, 40% Columbian coffee beans is blended and freeze dried at minus 60 degrees Celsius. A six ounce cup contains 100 calories, zero grams of fat . . . For those generation X'ers who are accustomed to a "loud" advertising style, the following will suffice: "Yo! This cup of joe will be blow you away. Be the first of your friends to drink this liquid gold and have the bragging rights that you, truly, have it together." As can be seen by these differing descriptions, a conservative individual would clearly be turned off by the in-your-face manner of the third data stream. Likewise, younger individuals would most likely be bored by the first description. In this manner, a company can cater to all needs without having to boil down and sanitize a particular Web page to meet a majority market, while alienating minorities.

The most beneficial aspect of the present invention which permits a company to tailor the delivery of information to a specific user without requiring the user to input a lot of mundane and unnecessary information will now be described in detail. When an individual accesses a particular Web page, the individual's current profile that the individual has selected, (for example 252A), is automatically downloaded to that Web page. The Web page manager matches the user's profile to the information identifier's 340A-340N. Depending upon the number of matches, the manager selects the data stream that corresponds most closely with the profile 252A. In this manner, the Web page manager tailors the Web page to the specific individual based on the profile. The Web page manager selects most appropriate data streams for the current information user 12, 14, 16, 18 depending upon the currently available data streams and the profile of the individual. Although there may be a standard Internet protocol developed which may require an information user 12, 14, 16, 18 to input their profile in a standard format such as 100 different sorting aspects, this is not required. The Web page manager will use those downloaded portions and will tailor the Web page accordingly.

This system allows the information provider to selectively provide information to the information user without the information user's knowledge or without irking the information user by telling them they need a password, or they need to be a member. It permits those members to get to the information seamlessly. For example, low end users may receive coupons, high end users may receive product warranty information Another feature of the present invention is that it includes the ability to access a web site and map the entire web site. For example, as shown in FIG. 2, when an information user selects choice 1 Ai, the person does not know what exists in choice 1 Ci until they get there. Often, the person forgets the other choices available. The present invention may either map the route which the person has gone and provide a tree and branch diagram as a picture-in-picture window within the screen or may map the entire web site upon accessing the Web page. For example, when a person access a web site, the web site navigator resident within the information user's browser may quickly go in and access every page of the web site. It will then summarize, and categorize the information in a concise manner and provide a branch and tree type map.

Although the invention has been described in part by making detailed reference to certain specific embodiments, such details is intended to be instructive rather than restrictive. It will be appreciated by those skilled in the art that many variations may be made in the structure and mode of operation without departing from the spirit and scope of the invention as disclosed in the teachings herein.

Although the features and elements of the present invention are described in the preferred embodiments in particular

# US 7,603,382 B2

combinations, each feature or element can be used alone (without the other features and elements of the preferred embodiments) or in various combinations with or without other features and elements of the present invention.

Hereafter, a wireless transmit/receive unit (WTRU) includes but is not limited to a user equipment, mobile station, fixed or mobile subscriber unit, pager, or any other type of device capable of operating in a wireless environment. When referred to hereafter, a base station includes but is not limited to a Node-B, site controller, access point or any other type of interfacing device in a wireless environment.

What is claimed is:

- 1. A system for providing web pages accessed from a web site in a manner which presents the web pages tailored to an individual user, comprising:
  - an interactive interface configured to provide dynamic web site navigation data to the user, the interactive interface comprising:
  - a display depicting portions of the web site visited by the user as a function of the web site navigation data; and
  - a display depicting portions of the web site visited by the user as a function of the user's personal characteristics.
- 2. The system of claim 1, wherein the display depicting portions of the web site visited by the user includes a map depicting a route of web pages visited by the user.
- 3. The system of claim  $\tilde{1}$ , wherein the display depicting  $^{25}$ portions of the web site visited by the user includes a map of web pages visited by the user, presented in a tree and branch diagram in combination with at least a portion of the entire web site accessible by the user.
- 4. The system of claim 1, wherein the display depicting portions of the web site visited by the user includes an indication of web pages visited by the user, presented as a picturein-picture window within the display in combination with at least a portion of the entire web site accessible by the user.
  - 5. The system of claim 1, wherein the interactive interface: includes a data file generated from user activity based on user data transmitted in response in part to user selections of a plurality of user-selectable fields, each field describing a personal characteristic of the user; and
  - is configured to automatically transmit data corresponding to the user selections upon initially accessing the web pages, wherein an analysis of the user selections provides a selection of a plurality of discrete web pages specifically tailored to the user; and the display depicting portions of the web site visited by the user includes data derived from at least one of the user data and user activity based on the user data.
- 6. The system of claim 1, wherein the interactive interface is further configured to generate a site map according to at least one of a route which the user has taken or a plurality of discrete sections tailored for the user, thereby providing a diagram in accordance with the user selections.
- 7. A method of generating a web page comprising:
- generating a plurality of data streams, wherein each data stream is associated with a particular portion of the web page, and wherein each data stream is stored in a computer memory; and
- changing at least one of the particular portions of the web page as a function of time.
- 8. The method of claim 7, wherein one of the particular portions presents a company logo, wherein the company logo is profiled by different symbols depending upon the time of
- 9. The method of claim 7, wherein the different symbols indicate the time of day.

- 10. The method of claim 7, wherein at least a part of one of the particular portions presents information associated with a company, wherein the at least part of one of the particular portions changes color for a certain period of time to indicate an event or condition associated with the company.
- 11. The method of claim 7, wherein the event or condition is associated with the price of products sold by the company.
- 12. The method of claim 7, wherein the event or condition is associated with the type of products sold by the company.
- 13. The method of claim 7, wherein the event or condition is associated with the price of stock associated with the company
- 14. The method of claim 7, wherein the event or condition is associated with employment opportunities offered by the is company.
  - 15. The method of claim 7, wherein the particular portions present different products at different times during each day.
  - 16. A method comprising:
  - receiving data which defines a plurality of user profile attributes in each of a plurality of user profiles;
  - storing the plurality of user profiles, each user profile comprising data descriptive of a user;
  - in response to a request from an information provider, transferring data from a specified user profile to the information provider; and
  - providing dynamic web site navigation data via an interactive interface, the interactive interface comprising:
  - a display depicting portions of a web site visited by the user as a function of web site navigation data; and
  - a display depicting portions of a web site visited by the user as a function of the plurality of fields having data descriptive of a user.
- 17. The method of claim 16, further comprising: transferring the stored plurality of user profiles to an information provider when a web page is accessed.
- 18. The method of claim 16, wherein data from the plurality of profiles are transferred in a standardized form.
- 19. The method of claim 16, wherein the plurality of user profiles include at least one of a business profile, a personal 40 profile, and a family profile.
  - 20. The method of claim 16, wherein the profile attributes include at least one of gender, race, income, and education.
    - 21. A method comprising:
  - receiving data from a user profile associated with a user; in response to a request associated with the user, sending a data stream that is selected based at least in part on the
  - received data from the user profile; and displaying the data stream via an interactive interface, the interactive interface comprising:
  - a display depicting portions of a web site visited by the user as a function of web site navigation data; and
  - a display depicting portions of a web site visited by the user based at least in part on the received data from the user
  - 22. The method of claim 21, further comprising:
  - selectively offering a coupon to the user associated with the request, wherein the coupon is based at least in part on the received data from the user profile.
  - 23. The method of claim 21, further comprising:
  - selectively presenting product warranty information to the user associated with the request, wherein the product warranty information is based at least in part on the received data from the user profile.

57) ABSTRACT

Instead of a PIN which is associated with an account and provides access to an account, a card identification code, which is located on the card but does not provide automatic access to an account, is used to verify that the consumer currently possesses the transaction card at the time of purchase and/or is the true card owner. At the time of card printing, an embossing file of account codes including associated identification codes is created and loaded into the account database. At the time of authorization, the identification code and the account code are entered into a POS device and sent to an authorization system. If the identification codes match, and other authorization parameters are satisfied, the transaction card is authorized.

# SYSTEMS AND METHODS FOR AUTHORIZING A TRANSACTION CARD

#### BACKGROUND OF THE INVENTION

#### 1. Technical Field

The present invention relates, generally, to transaction card fraud reduction systems and methods and, more particularly, to verifying that a consumer is in possession of a transaction card and/or is the true card owner during a 10 purchase transaction.

#### 2. Background Information

Transaction cards such as, for example, credit cards, debit cards, bank cards, charge cards, smart cards and the like, have become increasingly popular for purchasing goods and services and for conducting other transactions. A transaction card typically includes information related to the issuer's name and logo, an account number, an expiration date and the cardholder's name. The cards may also have other information, serial number and/or the like printed on the 20 card to represent other information about the transaction card or about the card member such as, for example, a group number, a promotion number, a card type number, a plastic issuance number and/or the like. Certain information is often embossed on the card with raised print, thereby allowing the 25 information to be imprinted on a charge slip; however, the information that is unembossed (flat) would not be imprinted onto the charge slip. For many transaction cards, the information printed on the card is also contained within a magnetic stripe, a bar code and/or an integrated circuit 30 (microchip) for automatic downloading/reading by a card reader.

Many card transactions are commenced by inserting, or sliding a card through, a card reader which automatically downloads the card information, thereby allowing the information to be used during the authorization process without the need for manual input or review of the card information. However, because of the substantial increase in fraudulent use and theft of transaction cards, the use of the card information is often supplemented by various fraud prevention techniques, such as requiring a signature to verify the consumer's agreement to the transaction or the entry of a PIN number to verify the consumer's authority to use the transaction card.

Additionally, certain card issuers, such as banks, incorporate the consumer's picture onto the face of the transaction card to give the merchant an additional verification procedure

While the use of a signature, PIN or picture is effective for  $_{50}$ fraud reduction when the cardholder presents a card to a merchant, these options are not as effective, and may not be available, for other transactions. Particularly, transactions which do not require face-to-face contact between a consumer and merchant, such as the use of a transaction card to 55 purchase items through the Internet or over the telephone (e.g., mail order). Moreover, many transactions may be alternatively completed without using the physical transaction card. For example, a consumer or merchant may simply key in the transaction card number into the keypad of a POS 60 device or the keypad on an ATM.

When conducting Internet, telephone or keypad transactions, a cardholder may only need to provide a card account number and expiration date to allow the merchant to charge a particular account and verify that the transaction 65 card is valid. Other verification information, such as a PIN number, is usually not disclosed because the PIN is typically

memorized by the cardholder and never disclosed to anyone. Because merchants often only request limited information to conduct a transaction over the Internet or the telephone, an increased potential for fraud exists due to the increased availability of this general information. In other words, regardless of a consumer's possession of the physical transaction card, a consumer can still fraudulently obtain and provide this general information.

Particularly, cardholders often provide a transaction card number to telemarketers, merchants, bank tellers and Internet sites, thereby allowing a merchant or clerk to retain the credit card number and associated information for later fraudulent use. Moreover, a person may overhear a transaction card number being disclosed over the telephone or, with the increase of mailbox thefts, a person may obtain a credit card number from a billing statement or promotional literature. Furthermore, advanced computer operators are able to intercept transaction card numbers which are transmitted over modems and/or the Internet. Accordingly, when a merchant simply requests a credit card number from a consumer, it is difficult for the merchant to ensure that the consumer placing the order has the transaction card in his or her possession and/or is the true cardmember, rather than using a stolen account number.

As stated above, the use of PIN numbers are typically limited to face-to-face or ATM transactions wherein the consumer personally enters a PIN into a keypad and the merchant does not need to have knowledge of the PIN. In non face-to-face transactions, the PIN would need to be disclosed to the merchant. However, due to security concerns, consumers prefer to not disclose their private PIN number to merchants and especially prefer to not disclose the PIN number over a telephone or through the Internet. Particularly, a PIN number is directly associated with the account number, and as such, may provide increased access to a transaction card account during a fraudulent transaction. Accordingly, a system is needed which allows the consumer to disclose a security number which is associated with the account number, but does not allow automatic access to the account.

## BRIEF SUMMARY OF THE INVENTION

Due to security concerns during non face-to-face commercial transactions, consumers prefer to not disclose their private PIN number to merchants and especially prefer to not disclose the PIN numbers over a telephone or through the internet. Instead of a PIN which is associated with an account and provides access to an account, a card identification code, which is located on the card but does not provide automatic access to an account, is used to verify that the consumer currently possesses the transaction card at the time of purchase and/or is the true card owner.

Along with the account number, a transaction card includes a non-embossed four-digit or three-digit number, called a card identification code. During creation of a transaction card, a five-digit identification code is calculated from the account number, four-digit or three-digit identification code and the expiration date based upon a predetermined algorithm. A four-digit identification code is printed on the front of the card, an associated five-digit identification code is entered into the magnetic stripe and an associated three-digit identification code is printed in the signature panel. An embossing file of account numbers including associated identification codes is created and loaded into the account database. At the time of authorization, the four-digit number on the front of the card and the account number are

manually keyed into a POS device and sent to an authorization system. The four-digit number is matched to the four-digit number on file for that transaction card. If the four-digit numbers match, and other authorization parameters are satisfied, the transaction card is authorized.

Alternatively, when the card is swiped through a POS device, the five-digit number previously entered into the magnetic stripe, along with other information, is automatically transmitted to the authorization system. The five-digit number is decomposed using a mathematical algorithm, and 10 the resulting three-digit and/or four-digit numbers are matched against the database record (which includes the originally assigned three or four-digit identification codes for the account number). If the respective three or four-digit numbers match, and other authorization parameters are 15 satisfied, the transaction card is authorized.

Thus, the entry of an additional identification code helps verify that the consumer currently possesses the transaction card at the time of purchase or is the true card owner, rather than simply using a stolen account number. Accordingly, requiring entry of an identification code along with the account number provides an effective deterrent to fraudulent use of the account number. For example, systems and methods in accordance with the present invention at certain tested locations have provided fraud reduction of approximately 78%.

## BRIEF DESCRIPTION OF SEVERAL VIEWS OF THE DRAWINGS

The subject invention will hereinafter be described in conjunction with the appended drawing figures, wherein like numerals denote like elements, and;

FIG. 1 is an exemplary flow diagram of the card creation and identification code creation process;

FIG. 2a is a front view of an exemplary transaction card showing an account number and card identification code;

FIG. 2b is a rear view of an exemplary transaction card showing magnetic strip and card identification code;

FIG. 3 is an exemplary schematic diagram of a simplified transaction card authorization system;

FIG. 4 is an exemplary schematic diagram of an authorization database with associated identification codes in

FIG. 5 is an exemplary flow diagram of the authorization process.

#### DETAILED DESCRIPTION OF THE INVENTION

To reduce fraud when conducting commercial transactions (i.e., the purchase of goods and services) using a transaction card 10, the present system requests entry of an additional number to help verify that the consumer has 55 possession of the transaction card at the time of purchase or is the true card owner, rather than simply using a stolen account code. Wherein a PIN number is typically memorized and not written down, the present number, called a card identification code 14, 15 and 16, is preferably printed on or 60 encoded in transaction card 10. Due to security concerns during non face-to-face transactions, consumers prefer to not disclose their private PIN number to merchants and especially prefer to not disclose the PIN number over a telephone or through the Internet. Instead of a PIN which is 65 associated with an account and provides access to an account, a card identification code 14, 15 and 16, which does

not provide automatic access to an account, is used to help verify that the consumer currently possesses the transaction card at the time of purchase and/or is the true card owner.

With momentary reference to FIG. 2a, in accordance with 5 the present invention, a transaction card 10 includes any device suitably configured to display an account code 12 and a card identification code 14. In a preferred embodiment, the transaction card is a credit card, charge card, debit card, smart card, bank card and/or the like. Transaction card 10 preferably includes information for conducting a transaction. In a preferred embodiment, the front face of transaction card 10 includes an account code 12 and a card identification code 14 located above account code 12. Account code 12 includes any number of characters (n characters) comprising any combination of numbers, letters, symbols or other indicia which are suitably configured to identify a transaction account. In a preferred embodiment, account code 12 is a 15-digit number which identifies an account code, including a routing number or other similar transaction numbers, corresponding to the card owner. One of ordinary skill in the art will appreciate that account code 12 may be associated with an individual account, a corporate account, an organization account, or any other entity and the account may represent a charge account, a credit account, a debit account, an electronic purse account, or any other financial account.

Card identification codes 14, 15 and 16 include any number of characters (n characters) comprising any combination of numbers, symbols, letters, or other indicia suitably configured to provide verification that the consumer has an actual card in possession at the time of purchase and/or is the true card owner, rather than simply using a stolen account code. In a preferred embodiment, card identification code 14 is printed on or encoded in transaction card 10. Card identification code 14 may be located on either side of the card, encoded into a medium on the card and may be 35 embossed (raised lettering) or unembossed (flat) into the plane of the card. In a particularly preferred embodiment, card identification code 14 is located on the front face of transaction card 10 on the same side as, and above, account code 12. Moreover, card identification code 14 is preferably a four-digit, unembossed (flat) number printed within the plane of the card. One skilled in the art will appreciate that, along with other card member information, card identification codes 14, 15 or 16 may be initially printed on many transaction cards 10 before, during or after account code 12 accordance with an embodiment of the present invention; 45 is printed on transaction card 10. In a preferred embodiment, card identification codes 14 or 15 are logically related to card identification code 16.

> After a consumer is approved for a transaction card, an account code 12, a four-digit identification code 14 and/or a three digit code 15, an expiration date 13 and other information are associated with the consumer's name in an account database 30 (see FIGS, 2a and 3). With reference to FIGS. 1 and 3, account code 12, a four-digit identification code 14 (or a three-digit identification code 15), an expiration date 13 and other information from account database 30 are preferably transmitted to a card creation system 32 (step 38). In a preferred embodiment, at the time of creating transaction card 10 for the consumer in accordance with the present invention, a five-digit identification code 16 is suitably calculated from account code 12, four-digit identification code 14 or three-digit identification code 15 and expiration date 13 based upon a predetermined algorithm (step 40). Five-digit identification code 16 is preferably calculated and encoded into the magnetic stripe because five-digit identification code 16 provides additional security by not being disclosed on the face of the card (only four-digit code 14 or three-digit code 15 are visible).

After determining identification codes 14, 15 and 16, transaction card 10 is preferably created with an embossed account code 12, embossed expiration date 13, embossed consumer's name 11 and non-embossed card identification codes 14, 15 and 16 (step 42). Particularly, in a preferred embodiment, a four-digit identification code 14 is printed (non-embossed) on the front of card 10 above account code 12, an associated five-digit identification code 16 is encoded into the magnetic stripe and an associated three-digit identification code 15 is printed in the signature panel. One 10 skilled in the art will appreciate that any one of the aforementioned card identification codes 14, 15 and 16 may exist throughout this process alone or in any combination with the other card identification codes. For example, only identification code 14 may appear on the front of the card without 15 identification codes 14, 15 and 16. any codes on the back of the card or in the magnetic stripe. Moreover, identification codes 14, 15 and 16 may comprise any number of digits, symbols, characters, letters and/or the like and may be located in any location and in any medium on card 10. For example, an identification code may be 20 encoded into an integrated circuit in a smart card embodi-

Upon printing of transaction cards 10, an embossing file 34 including card identification codes 14, 15 and 16 is created (step 44). Embossing file 34 with associated iden- 25 tification codes 14, 15 and 16 is next uploaded into account database 30 (step 46). In a preferred embodiment, authorization server 26 communicates with, and analyzes the data within, account database 30 (step 48). Alternatively, the use of a Hardware Security Module allows embossing file 34 to provide a simplified, more direct transmission of embossing information to account database 30 without the need for maintenance uploads. In a particularly preferred embodiment, as shown in FIG. 4, identification codes are stored in a look-up table within account database 30.

Referring to FIG. 3, an exemplary authorization system 20, account database 30 and card creation system 32 is shown. Authorization system 20 is any authorization system suitably configured to authorize a transaction card and notify an input device 22 of the authorization status. One skilled in 40 the art will appreciate that authorization system 20 can be an existing authorization system, such as the Central Authorization System used by American Express, which is re-programed or re-configured to preform the functions of the present invention or is a system specially configured to 45 preform the functions of the present invention. In a preferred embodiment, authorization system 20 includes input device 22, network 24 and authorization server 26. input device 22 is any device suitably configured to accept transaction information and transmit the information for approval. In a 50 preferred embodiment, input device 22 is a telephone, computer, point-of-sale terminal, ATM and/or the like. Input device 22 preferably communicates with network 24, wherein network 24 is any device or software suitably configured to transmit information. In a preferred 55 embodiment, network 24 is a modem, a PSTN, an Internet, an Intranet, a direct link, or any combination thereof.

With continued reference to FIG. 3, network 24 provides a communication link between input device 22 and authorization server 26. Authorization server 26 is any device 60 suitably configured to authorize a transaction and/or transaction card and notify input device 22 of the authorization status. In a preferred embodiment, authorization server 26 is a centralized authorization system including transaction account codes. One skilled in the art will appreciate that 65 authorization server 26 can be a centralized database providing authorization information to various input devices 22.

Moreover, one skilled in the art will appreciate that authorization server 26 may include any combination of components, software, servers and computers suitably configured to not only authorize transactions and/or transaction cards, but also to provide additional transaction support such as report generation and promotional programs. Authorization server 26 is preferably in communication with, and interrogates, account database 30. One skilled in the art will appreciate that account database 30 can be a separate component, integrated into authorization server 26 or simply software within authorization server 26 or within input device 22. In a preferred embodiment, account database 30 includes a look-up table (see FIG. 4), thereby allowing verification of the association between account codes 12 and

Referring to FIG. 5, when a consumer uses transaction card 10, a clerk, sales representative, merchant, consumer or other authorized person inputs account code 12 and card identification code 14, 15 or 16, along with any other transaction information such as purchase amount, etc., into input device 22 (step 50). In one embodiment, card identification code 14 or 15 is manually keyed into input device 22. The keyed information is sent via network 24 to authorization server 26 (step 25 51). Authorization server 26 suitably determines if the data was keyed in or swiped through input device 22 (step 52). In a preferred embodiment, to help determine if the data was keyed or swiped, the keyed data includes different formatting, uses different communication lines, different number of digits in the identification code and/or different header information than information read from the magnetic stripe,

After authorization server 26 determines that the information is manually keyed information, authorization server 26 suitably interrogates account database 30 to determine if the keyed identification code 14 or 15 matches the respective identification number on file for that transaction card (step 54). If the respective identification codes 14 or 15 match, the authorization process proceeds to determine if other authorization parameters are satisfied (step 58). If the respective identification codes 14 or 15 do not match, the transaction is denied and an "invalid Card ID" message is transmitted to the input device 22 (step 60). In an alternative embodiment, if the identification numbers do not correspond, authorization server 26 preferably prompts input device 22 to re-enter the card identification code and the process is repeated. If the numbers do not correspond again, transaction card 10 is denied.

When the card is swiped through a POS device 22, the five-digit number previously entered into the magnetic stripe, along with other information, is automatically transmitted to authorization server 26. Authorization server 26 suitably determines that the data originated from a magnetic stripe (step 52) by various methods such as, for example, data format, communication lines from which the data was sent, header information and/or the number of digits in the identification code. Authorization server 26 preferably decomposes the five-digit identification code 16 into a four-digit number using a predetermined mathematical algorithm (step 56). In a preferred embodiment, this algorithm is the inverse of the algorithm set forth above used to create the five-digit identification code 16. Alternatively, account database 30 includes five-digit identification codes 16 for each account code 12, thereby eliminating the need to transform the five-digit code 16 to a four-digit code 14. The algorithm is optimally a robust and secure algorithm which conforms to the Data Encryption Standard. Similar to above, authorization server 26 then suitably interrogates account data-

# US 6,182,894 B1

base 30 to determine if the derived four-digit number 14 matches the four-digit number on file for that transaction card (step 54). If the fourdigit numbers match, the authorization process proceeds to determine if other authorization parameters are satisfied (step 58). If the four-digit numbers 5 do not match, the transaction is denied and an "invalid Card ID" message is transmitted to the input device 22 (step 60). In an alternative embodiment, if the numbers do not correspond, authorization server 26 preferably prompts input device 22 to re-swipe the card identification code 16 and the process is repeated. If the numbers do not correspond again, transaction card 10 is denied.

In a further alternative embodiment, the incorporation of card identification code 14 into a particular authorization process is optional depending on the type of transaction card 15 10 or account code 12 used for the financial transaction. In other words, when authorizing a transaction, the same authorization system 20 may not require a card identification code 14 for particular account codes 12. For example, certain consumers may be enrolled in a promotional program which includes a cardless account without a card identification code 14. As such, while other verification means typically exist, authorization server 26 may not require entry of an identification code or account database 30 may include any suitable automatic authorization for 25 five-digit number. certain ranges of account codes 12, regardless of entry of a card identification code 14.

In a preferred embodiment, account codes 12 arc subject to periodic update as new card promotions or new accounts are opened. For security reasons, card identification codes 30 14, 15 or 16 are preferably only retained in authorization server 26 until authorization or rejection is received by input device 22. Moreover, in a preferred embodiment, card identification codes 14, 15 or 16 are not permanently stored in the input device 22 or the authorization server 26 and are 35 not printed on documents (i.e., receipts, tickets, itineraries, etc.).

Although the invention has been described herein in conjunction with the appended drawings, those skilled in the art will appreciate that the scope of the invention is not so 40 limited. Modifications in the selection, design and arrangement of various components and steps discussed herein may be made without departing from the scope of the invention as set forth in the claims. Moreover, the present invention may be described herein in terms of functional block com- 45 ponents and various processing steps. It should be appreciated that such functional blocks may be realized by any number of hardware components configured to perform the specified function. For example, the present invention may employ various integrated circuit components, e.g., memory 50 elements, digital signal processing elements, look-up tables, and the like, which may carry out a variety of functions under the control of one or more micro-processors or other control devices.

In addition, those skilled in the art will appreciate that the 55 present invention may be practiced in any number of data communication contacts and that the authorization system described herein is merely one exemplary application for the invention. Further, it should be noted that the present invention may employ any number of conventional techniques for 60 data transmission, training, signal processing and conditioning, and the like. Such general techniques that may be known to those skilled in the art are not described in detail herein.

We claim:

 A system for authorizing commercial transactions comprising:

- a transaction card having an n character account code and an n character identification code, wherein said identification code is not an expiration date and wherein said account code and said identification code have a predetermined logical relationship;
- an input device for receiving said account code and said identification code; and,
- an authorization computer in communication with said input device, said authorization computer configured to confirm said predetermined relationship between said account code and said identification code.
- 2. The system of claim 1, wherein said transaction card is at least one of a credit card, debit card, bank card, charge card and smart card.
- 3. The system of claim 1, where in said identification code is unembossed.
- 4. The system of claim 1, wherein said account code and said identification code are on the same side of said transaction card.
- 5. The system of claim 1, wherein said input device is at least one of a keypad, POS terminal, ATM terminal, computer and telephone.
- 6. The system of claim 1, wherein said identification code is at least one of a three-digit number, four-digit number and
- 7. The system of claim 1, wherein said account code and said identification code are on the same side of said transaction card and said identification code is an unembossed four-digit number located above said account code.
- 8. The system of claim 1, wherein said authorization computer is configured to transform said identification code to a second identification code,
- 9. The system of claim 1, wherein said authorization computer communicates with an account database and said authorization computer is configured to confirm said predetermined relationship between said account code and said identification code by interrogation of said account database.
- 10. A method for obtaining an authorization for a commercial transaction comprising:
- keying an n character account code and an n character identification code into an input device, wherein said identification code is not an expiration date and wherein said account code and said identification code have a predetermined logical relationship;
- communicating, from said input device to an authorization computer, said account code and said identification code; and,
- receiving a confirmation from said authorization computer of said predetermined relationship between said account code and said identification code.
- 11. The method of claim 10, wherein said keying step includes keying said n character account code and said n character identification code into said input device, wherein said input device is at least one of a keypad, POS terminal, ATM terminal, computer and telephone.
- 12. The method of claim 10, wherein said keying step includes keying said account code and said identification code which are located on a transaction card, further wherein said account code and said identification code are printed on the same side of said transaction card and said identification code is an unembossed four-digit number located above said
- 13. The method of claim 10, further comprising transforming, via said authorization computer, said identification code to a second identification code.
- 14. The method of claim 10, further comprising communicating between said authorization computer and an

# US 6,182,894 B1

account database and confirming, via said authorization computer, said predetermined relationship between said account code and said identification code by interrogating said account database.

- 15. A transaction card for authorizing commercial trans- 5 actions comprising:
  - an n character account code in a first field;
  - an n character identification code in a second field, wherein said identification code is not an expiration
  - wherein said account code and said identification code have a predetermined logical relationship;
  - said transaction card configured to provide, via an input device, said account code and said identification code 15 to an authorization computer, wherein said authorization computer is configured to confirm said predetermined relationship between said account code and said identification code.

10

- 16. The system of claim 15, wherein said transaction card is at least one of a credit card, debit card, bank card, charge card and smart card.
- 17. The system of claim 15, wherein said account code and said identification code are on the same side of said transaction card and said identification code is an unembossed four-digit number located above said account code.
- 18. At an authority responsible for authorizing a transaction, a computer-implemented method for handling an authorization request, comprising the following steps:
  - receiving an n character account code and an n character identification code from an input device, wherein said account code and said identification code have a predetermined logical relationship;
  - confirming said predetermined relationship between said account code and said identification code; and,

\* \* \* \*

processing the authorization request.

## (57) ABSTRACT

A credit facility for controlling financial transactions is arranged with the ability of users to establish self-imposed limits on a category by category basis. The processing system provides messages and other information to the user, both on-demand and at the point of sale, based upon the category of the transaction and the limit set for that category. In one embodiment, both the user and, if desired, third parties, can obtain or be notified, of account balances on a category by category basis. Also, the main user can assign category limits, or prohibitions, on sub-users of the same account. In one embodiment, information pertaining to a specific transaction is communicated to a third party.

#### ADMINISTRATION OF FINANCIAL ACCOUNTS

#### RELATED APPLICATIONS

This application claims priority to U.S. application Ser. No. 11/567,044 which, in turn, is a divisional of and claims priority to U.S. application Ser. No. 10/192,426, now U.S. Pat. No. 7,254,548. This application also claims priority to U.S. patent application Ser. Nos.: 11/567,032; 11/767,246; and 11/567,069, all of which claim priority to U.S. Pat. No. 7,254,548. The subject matter of U.S. Pat. No. 7,254,548, and application Ser. Nos. 11/567,044; 11/567,032; 11/767,246; and 11/567,069 is expressly incorporated by reference herein.

#### BACKGROUND

The popularity of credit cards, debit cards, and other facilities for financing transactions for the consuming public at the point of sale is now without question. It is easy, and all too 20 prevalent, that along with such popularity and case of use of most point of sale credit facilities, comes financial difficulty for many people.

It is difficult, even for the most disciplined person, to resist the temptation of purchasing a product spontaneously. This 25 and can change the limits when desired, by telephone, email, impulse buying is often encouraged by merchants and, when done well, is highly effective.

Today, most credit facilities, such as credit cards, have ultimate spending limits, such that when the limit is exceeded (or the most recent invoice not paid promptly) the consumer 30 user is denied further access to credit. Usually, by this time, the consumer is in financial distress.

Many credit facilities today allow consumer users to obtain current balances, as well as recent purchase information, by telephone or Internet, or other on-line access. This historical 35 data does not adequately address the problem, as it does not help the consumer in making purchasing decisions at the time a purchase decision is being contemplated. Also, many credit facilities give annual print-out summaries of purchases by category. While such reports are nice to have at tax season, or 40 for next year's planning, they are a backward-looking view and do not serve to help the consumer on a day-to-day basis. People on fixed incomes, low incomes and people with debt "problems," should be on rigid budgets and may require current financial information in a more timely manner. People 45 striving simply to "watch" their spending also require current information, if they are to make intelligent buying decisions.

Another problem exists today when some users have the use of a card issued to another person. For example, in an employer/employee situation often an employee is given use 50 of a credit card for the purchase of goods or services which are business related. Unfortunately, such credit facilities are sometimes misused, or the balances go too high, and by the time the employer learns of the problem it may be too late to remedy the situation.

#### SUMMARY

This Summary is provided to introduce a selection of concepts in a simplified form that are further described below in 60 the Detailed Description. This Summary is not intended to identify key features or essential features of the claimed subject matter, nor is it intended to be used to limit the scope of the claimed subject matter.

Various embodiments are directed to a system and method 65 which allows consumer users to establish self-imposed limits on the user's spending (borrowing) such that when the limit is

2

reached the consuming user is notified. This notification can be before, during or after the point of sale transaction, and can be delivered, if desired, by the account clearing network and printed on the user's purchase receipt. The notification message can be delivered via a phone call, email or over an Internet connection to the user. The notification can be to one or more designated third parties, such as a parent, or card owner, or a debt counselor.

In at least one embodiment, the user will pre-establish self-imposed spending limits (guidelines) on a category by category basis, and each category can have, if desired, a different accounting period. For example, the food category can have a monthly (or weekly) limit, while the hobby category can have, for example, an annual or semi-annual limit. Since these limits are self-imposed, they do not impact the user's ability to complete any transaction, but rather they serve to provide the user meaningful information at a time when that information is most useful.

In another embodiment, the user may access his/her account, other than at the point of sale, to see (or hear) a running total of category balances, based on accounting periods, as well as comparisons against the user imposed preestablished category by category budget.

In another embodiment, the user can establish the limits, Internet or the like. Also the limits need not be constant from accounting period to accounting period. Thus, if a person's ability to repay the charged (borrowed) amount fluctuates during the year, the user may pre-establish that the limits will automatically change during those periods. Also, the user might decide that if his/her total outstanding balance reaches a certain amount, certain budgeted categories then will be reduced until the total unpaid amount recedes below the "critical" level. In this regard different categories can be given different priorities.

For example, assume a user has a total line of credit of, say, \$5,000. Also assume that the user has established that his/her food budget is to be \$200 per week (with the highest priority set), and that the boat budget is \$1,000 per year (with the lowest priority set). Also let us assume that the user has set a self-imposed arbitrary cap on his/her outstanding credit card balance of, \$2,000, let us assume also that the current outstanding balance has exceeded the self-imposed \$2000 limit, but has not reached the \$5,000 card limit.

Now let us assume that the user desires to buy a new \$100 fishing rod for his boat and this will be the first "boat" purchase this year. The user can access his account in any number of ways, for example, by voice, or by Internet or at the point of sale. When the user accesses the account, since the selfimposed outstanding balance cap of \$2,000 has been exceeded, the user will be informed that the available budget for the fishing rod is zero, even though the available budget amount is \$1,000 and even though the line of credit still allows for \$3000 worth of spending. Note, that had the user inquired about a food category he/she would have been told the actual amount available (or the actual amount used, if desired) in the "food" category.

In a still further embodiment, the user may establish subusers on his/her account and may authorize each user to use the account only with respect to certain categories, or category amounts, or only up to a certain credit limit, or only for a certain period of time, or a combination of the above.

The foregoing has outlined rather broadly the features and technical advantages of the various embodiments in order that the detailed description of the embodiments that follows may be better understood. Additional features and advantages will be described hereinafter which form the subject of the

3

claimed subject matter. It should be appreciated by those skilled in the art that the conception and specific embodiments disclosed may be readily utilized as a basis for modifying or designing other structures for carrying out the same purposes of the described embodiments. It should also be 5 realized by those skilled in the art that such equivalent constructions do not depart from the spirit and scope of the claimed subject matter as set forth in the appended claims. It is to be expressly understood that each of the figures is provided for the purpose of illustration and description only and is not intended as a definition of the limits of the claimed subject matter.

#### BRIEF DESCRIPTION OF THE DRAWINGS

For a more complete understanding of the claimed embodiments, reference is now made to the following descriptions taken in conjunction with the accompanying drawing, in which:

FIG. 1 shows a block diagram of one embodiment where the credit-card user is making a purchase at a point of sale located at a merchant's premises;

FIG. 2 shows a block diagram of another embodiment where the credit card user is making a purchase, editing a 25 profile or obtaining account information via an on-line Internet (or telephone) connection;

FIGS. 3A and 3B show one embodiment of an operation where the user obtains information from and/or edits his/her profile;

FIG. 4 shows one embodiment where the processing system, in response to a request, provides a message and/or blocks the transaction dependant, in part, upon the information contained in the user's profile;

FIGS. 5 and 6 show embodiments of profile data bases on 35 a category by category basis; and

FIG. 7 shows one embodiment of a user account organized by category.

#### DETAILED DESCRIPTION

Turning now to FIG. 1, there is shown System 10, which is one embodiment showing user 100 with credit card 11, getting ready to insert the card into card reader 12 to complete a sales transaction at a point of sale. The information from card 45 reader 12 is communicated via communications links 14.1 and 14.2 and network 101 to central processor 15. Processor 15, in conjunction with database 16 and profiles 17, then categorizes the various purchases being made and stores those purchase amounts and categories in database 16, 50 according to profiles of user 17, as stored, for example, in profile data base 17.

As will be discussed, these profiles can include not only the budget amounts for each category, but what types of items would fit into the different categories. Based upon the pro- 55 files, processor 15 then can communicate in one or more of several ways, such as, for example, back over communications links 14-1, 14-1 to user 100 or over alternate communication paths via auxiliary communication 18. This communication can be, for example, via printer 13, or it can be via 60 auxiliary communication path 18. Auxiliary communication 18 can be, for example, to the user via cell phone, pager, or other device. At the same time, if desired, third parties, such as parents, employers, debt counselors and others, could also be notified. This communication can, if desired, occur for all 65 purchases, or for certain of the purchases by category or by amount.

The system can be designed, if desired, such that if the amounts in a category (or if the total outstanding balance at that time) were to exceed a certain amount, user 100, or a third party as identified in the user's profile, would be required to give specific approval for a particular purchase. This system could be extended so that third parties (such as parents) can allow a child to use a credit card, but certain purchases over a certain amount, or all purchases, or purchases in certain categories, will require approval from the parent (or other third party), who would not actually be present at the point of sale.

For example, a parent could allow a child to have a credit card for the purpose of buying clothes. The child then selects his or her purchases at a location and runs card 11 through the card reader at the point of sale. The system, via profile 17, 15 database 16 and processor 15, then recognizes that this is a card which is a sub-account card of a main account, or an account that is otherwise special to this person. Processor 15 then enables a communication to the third person identified by profile 17 via auxiliary communication 18. This communication could be, for example, cellular, landline, Internet, pager, PDA, or the like. The purchase can only be completed, if the third person responds in a positive manner (perhaps by pushing a button or speaking an acceptance word as set out in the user's profile). Processor 15, perhaps working in conjunction with other network processors, controls the acceptance back to the point of sale.

In some situations, it could be appropriate for the item that is being purchased to have a picture, available either in an auxiliary database 16-1, or transmitted from the point of sale at the time of purchase, transmitted to a third person, either for approval or simply for information purposes. This would be helpful, for example, when a husband is buying a suit and wants his wife to see the suit before the purchase is consummated. A picture of the suit could be captured by camera 12-1, communicated over the communication link to processor 15, and then through auxiliary communication 18 to a designated third party at a cell phone, computer, pager, FDA, or the like.

In some situations, the purchaser may desire additional information, such as warranties, specifications, pictures, assembly instructions, to be sent to a specific location (such as the point of sale, or to his/her home), or the purchaser may wish to register his/her purchase with the seller, or even apply for a rebate, all at the time or purchase. Processor 15, working in conjunction with database 16 and profiles 17 then could send the purchaser's address and other information to the seller. The seller's information obtained from transmitted POS information, or from data contained at the central location, such as from auxiliary database 16-1, would be combined with the user's (purchaser's) information as obtained from database 16, and sent to the seller. Since the user specific database contains information pertaining to the user's prior purchases it could be used, for example to aid the purchaser in making new purchases, perhaps by providing compatibility information to the user, either at the POS or on demand. This compatibility information could be within system 10, but would likely reside with each specific seller and could be supplied to the user at the POS (or on demand) in response to the above-discussed purchase registration.

Note that auxiliary database 16-1 can hold any type of information that is desired to be communicated to either user 100 or to third parties. This information could be sound, video, or any type of information, and can be stored in compressed format in the well-known manner. Also the information sent to a third party could be, for example, pictures, video, color, audio or any combination thereof. In addition, the information could be partially located in the database, such as database 16-1 and available based upon some infor-

mation, perhaps a bar code or other information sent from card reader 12 or from camera 12-1.

In addition, the system could use camera 12-1 to take a live picture of user 100 at the point of sale and to then match that picture against a known picture or other information. This 5 could then be sent to a third party for verification based upon a profile in database 17. Thus, when a main user of a credit card allows other sub-users, which could be employees, children, relatives, temporary workers, to use the sub-account card, each purchase using the sub-account card could trigger, 10 if desired, the taking of a picture of the then user at the POS. This picture, or other information (such as a password) could be transmitted, under control of profile 17, database 16 and processor 15 to the main user, as discussed above, such that the transaction would not be completed until the main user 15 signified acceptance.

This system, for example, could be used to keep an account "open" for the real user for a period of time when a card is reported lost or stolen. In such an event, the profile would be used to provide the system with a special verification proce- 20 dure unique to the user. This verification could be for example, a password necessary at each purchase, or a biometric sent from the POS for comparison during each transaction.

System 10 could operate such that the main user, as will be discussed, can at any time change his/her profile, thereby 25 adding or changing passwords, and assigning passwords or other control information to the profile. These passwords could be for the main account, or for any sub-account. When the credit card is presented at a POS, system 10 would check the user's profile to see if any such passwords, third party 30 approvals, etc, are required. If so, the salesperson at the point of sale could then follow directions sent to that person via network 101 so as to obtain the proper identification of the user. This would give an added measure of security to credit card users. For example, the profile of a user might specify 35 that call-in purchases (ones where the card is not physically present at the POS location) will need to be verified by a specified password, or verified by a communication placed by the salesperson (or by system 10) to a third person. The user's own created profile will allow for flexibility in this regard.

Note that the profile of the user, including database information if desired, could be stored on the user's card along with, if desired, at least some of the processing. In such a scenario, information from the profile would be sent to a central processing network to provide the services for the user 45 as discussed above. A so called "smart card" would be one method of accomplishing this objective.

Turning now to FIG. 2, there is shown System 20 in which user 200 is utilizing keyboard 22 and computer 23 to access his or her account via communication links 201-1 and 210-2 50 and public network 24 to web portal or phone operator 25. Portal 25 then accesses processor 15 via communication link 202-1. Such accessing of the system by user 200 could be for the purpose of obtaining account information at any time on a category by category basis, or for establishing (as will be 55 discussed) various account categories, balances and sub-users, or user 200 could be using computer 23 (which could be a telephone, pager, PDA, or the like) as a POS device. Note that connection 201-1, as well as the other connections shown, could also be by pager network, cellular network or 60 any other type of network, including for example, wireless, wire line or the cable satellite network typically utilized for broadcast signals into the home for entertainment purposes. Once connected to processor 15, the system operates as discussed above with respect to FIG. 1. In the situation where at 65 least a portion of the processing is on the user's smart card, then the user would insert his/her card at a reader (not shown)

associated with computer 23. Of course, if the smart card included wireless technology, such a reader would be unnecessary, both in FIG. 2 as well as in FIG. 1.

6

FIG. 3A shows system 30 which is one embodiment of a system utilized to enable system 10 (FIG. 1), or system 20 (FIG. 2) where a user can establish various categories and credit limits and/or view the existing account at any time. In process 301 the user logs onto the system as is well known. In process 302 the user is identified and is validated by the system. At this point the user is given several choices, three of which are shown in FIG. 3A. One such option, as shown in process 303, allows the user to view the account limits and current status. The user in process 304 could edit the profile and in process 305 the user may establish new profiles.

Assuming the user wanted to view the account limits, then the user in process 330 would select the desired information. The system in process 306 would access the processor and other databases and profiles to provide the desired information, via process 307, which could be in the form of FIG. 5, 6 or 7, or other profile information. If the user desired to just view the information, process 334, then when the user was finished, as shown by process 331, the connection would be terminated in a well known manner.

If changes were to be made, as controlled by process 334, then the user would be directed to edit profile process 304, and the user could either edit the main user or subusers. Assuming the main user is to be edited, the user is directed to the same path as would be utilized if there was to be established a new profile via process 305, such that the user, under control of process 307 would set the categories and limits for the main user.

Going back to process 308, had the main user decided to edit some profile other than the main user's profile, then the users would be identified via process 306 and the paths then would be concurrent for both the sub-users' and main user, such that process 309 would inquire as to whether some users would have different limits, categories, times or parameters.

If the answer was yes, then those parameters would be set for each user as to which category, amount, time or any other parameter desired for individual sub-users and the main user. If everybody were to have the same limits, then process 309 would skip to process 311 and the question would be answered as to whether there are automatic limits with timing changes to be applied. If there were, those parameters would be set via process 312. Process 312 would also control any other parameter that needed to be set, such as, by way of example, the user's home address, phone number, email address, auxiliary addresses (both physical and electronic), cell phone numbers, pagers, PDA addresses, third party notifications, together with their respective contact information, passcodes, special limits.

After the user is finished entering all of the desired parameters, the question would be asked as to whether the normal categories of purchase goods were to be used. By this it is meant that some categories would be preset by the system itself, such that clothes being purchased would always go under the clothing category. However, if desired, a user could decide that clothes from certain stores, or certain types of clothing, such as sporting clothes, would go under a sporting category. The user could decide, for example, such that certain foods would go under a discretionary category other than food. This can be seen in FIG. 6 where the natural category for, say ice cream, would be food, but a user could switch the natural category to a profile category of snack, if desired. Likewise, fishing gear would have a normal category of sporting goods, whereas this user would have a profile category of boating. This would allow a user to more finely tailor his or

Document 1-2

her profile to be more accommodating of the user's needs. It would allow a fine tuning of budgeting and expenses on an 'as you go' basis.

In process 314, the user can assign items to categories and can do so by sub-user if desired, so that certain sub-users can have access to all categories, or some categories, and also what items are included in those subcategories. For example, a parent may allow a child a credit card for the purchase of food, and restrict the child from buying alcohol or cigarettes. if so desired. Or, the parent could allow the child to have a 10 credit card for the purchase of gasoline for the family car, but other products sold at the service station would fall into a different category, either naturally or as a selection under the categories selected under process 314, such that only certain products such as gasoline could be purchased by certain users 15 of the credit card.

Continuing on FIG. 3B, if the user desired to set priorities for different categories, process 315, such that as discussed above, based upon the priority level set in process 316, and the trigger amounts in 318, the user would be notified of different 20 category levels such that the user is better able to maintain a strict budget when necessary. Since these limits are all selfimposed the user can determine, on a category by category basis, the difficulty and manner for overriding any "inhibiting" message.

In process 317 it is determined whether only the point of sale user is to be notified, and if so, how that notification is to be made via process 319. Notification can be printed on the receipt, or the notification can be by cellular phone call, email or other notification and can be contemporaneously with the 30 transaction or thereafter. If third parties are to be notified, then the names of the third parties and mode of notification can be set via process 321, all of which would be stored in database 16 and profile 17 (FIG. 1) via process 320.

Before exiting the system, the user may wish to edit the 35 profiles, perhaps to add other people or other categories, limits or the like. If so the system recycles back to process 304, FIG. 3A. If not, the user is finished with the profile.

Turning now to FIG. 4, there is shown system 40 which illustrates one embodiment of the point of sale transaction 40 where the user is in the process of buying a product using a credit facility. The user typically would have a card swiped through a reader, as discussed in FIG. 1. This operation is shown by processes 401 and 402. System 40 would then determine via process 403 whether the user has a profile, If 45 not, the system would proceed as normal, in the well known manner.

If the user has a profile, then the profile is accessed via process 404 and the profile then begins to control the transaction at the point of sale. If there is not a message is to be sent 50 to the user, or to a third party, and if no other special action is to be taken, then the system would proceed normally. If special POS actions are required, then the system would obtain any appropriate information from the point of sale via process 406. This information can be information from the 55 specific transaction, such as items purchased, categories, amounts of each item. Or it could be information pertaining to the user, such as for example, a picture of the user, iris scan, fingerprint, or other biometric. In this case the picture (or other information) of the user would become an item to be 60 stored and perhaps sent to third parties for verification of the transaction, or simply for record purposes. The information from the POS could be a user response, such as, for example, the mileage on a car. This information could then be used by the system to calculate the user's gas mileage (miles per 65 gallon) based on "Gas" category purchases and user supplied information.

If necessary, process 407 would utilize POS information, such as bar codes or other category information, to then obtain other data from a data base. For example, based upon a bar code obtained from the POS, information could be sent back to the user at the POS or could be forwarded to one or more third parties, perhaps for verification, or for registration, or the like. Pictures of the purchased items could be obtained, along with specifications, warranty information, last minute updated information (such as usually contained in a Read Me file) and sent to the customer at the point of sale, if desired. If a message is to be sent to a third party via process 408, then this message is either sent or posted via process 409. Another example, would be for the system, based on profiled information, to send third party and address information back to the user, perhaps so that the user can send a purchase to the third party.

If the system must wait for verification from a third party, as contained in process 410, then process 420 controls this waiting period and the POS transaction stops until the desired information is returned. This information could be approval or other information from third parties, or it could be service contract information, specification information, or other types of information desired by a customer.

Then it is determined if a message is to be sent to the user. This message could be the overall account balance, or a category account balance, or if desired a summary of category balances. This information can be delivered before the completion of the transaction, or afterward, and it could be contained on a receipt generated at the POS or it could be a communication to a third party, all determined by the profile of the user.

Process 412 controls as to whether the transaction is to be inhibited in any manner. If it is, inhibiting (or blocking if desired) is controlled by processes 416 and 417. If it is not to be inhibited, a determination must be made if a message is to be sent to the user at the point of sale, or other places as controlled by processes 413, 414, 415, 418 and 419. If the transaction is to be inhibited, this is controlled by processes 416 and 417, all under pre-control of the user.

FIG. 5, as discussed above, shows different categories, codes for categories, amounts that the user has decided upon, the priority of the category, the accounting period for the priority, and how much the category can be adjusted and when the adjustment would occur.

For example, in the food category, the amount is \$200.00 per week, but during the months of July and August, this is adjusted by \$100.00 to take into account the different food intake needs of the family during vacation periods. In this case, all users have access. Code 4, which is restaurants, is a monthly account of \$200.00 for eating out at restaurants. It is adjusted by \$300.00 during the month of July, and the only user that can use it is the A user. The boat account is \$1,000.00. It is a semi-annual amount and has a priority 3, which if desired, means that if other categories are over at a particular time when the boat account is to be used this account will be inhibited (subject to being overridden by the user) until the overall account balance goes below a certain amount.

As shown in the example, only the B user can buy purchases in the boat account. For this user account alcohol is a code inhibited for all users. Thus this account, regardless of who the user is, cannot buy alcohol because of the selfimposed prohibition. Of course, such prohibitions could apply to any category, such as tobacco, movies, etc., as established by the user of the account. These prohibitions can be on

a category by category basis and can be more finely granulated so that sub-user accounts can each have different permission levels if desired.

FIG. 6 shows different natural categories that have been changed to the profile categories, depending upon the specific 5 needs of this user. Thus, when the system processes purchases in certain natural categories, these categories are "translated" into the categories that the user desires. Thus, as discussed above, instead of ice cream being classified as a food, for this user, ice cream would be accounted of in the category called 10 snacks.

FIG. 7 shows a sample printout of information that is available to the user on demand of the user. This information can be periodically delivered to the user, or the user can obtain the information on-line via, for example, the Internet. The 15 available information shows usage by category according to the specific profile of the user. This then allows the user to plan purchases and to know at any time where the user is with respect to the user's own budget.

Of course, FIG. 7 can be arranged in any way and the 20 information can be provided in different formats, and it even could be arranged as the user would like it to be, based upon user designed formats.

It should be noted that while the example discussed above is an example using a credit card, the term credit facilitation 25 system can be a credit card, a debit card, a smart card or even a card issued by a specific store, chain or organization for the purpose of providing discounts and/or identity for particular users.

Although the described embodiments and their advantages 30 have been described in detail, it should be understood that various changes, substitutions and alterations can be made herein without departing from the spirit and scope of the claimed subject matter as defined by the appended claims. Moreover, the scope of the present application is not intended 35 medium. to be limited to the particular embodiments of the process, machine, manufacture, composition of matter, means, methods and steps described in the specification. As one of ordinary skill in the art will readily appreciate from the disclosure, processes, machines, manufacture, compositions of matter, 40 means, methods, or steps, presently existing or later to be developed that perform substantially the same function or achieve substantially the same results as the corresponding embodiments described herein may be utilized according to the present teachings. Accordingly, the appended claims are 45 intended to include within their scope such processes, machines, manufacture, compositions of matter, means, methods, or steps.

What is claimed is:

1. A system comprising:

means for storing a profile keyed to a user identity and containing one or more user-selected categories to track transactions associated with said user identity, wherein individual user-selected categories include a user pre-set limit; and

- means for presenting transaction summary data for at least one of the one or more user-selected categories, said transaction summary data containing said at least one user-selected category's user pre-set limit.
- 2. The system of claim 1, wherein the individual user- 60 selected categories further include one or more purchasable items.
- 3. The system of claim 2 further comprising means for assigning individual purchasable items to one or both of: a natural category or a user-specified category.
- The system of claim 1, wherein said at least one userselected category is associated with one or more user-selected

10

sub-user identities, and wherein said transaction summary data includes one or more sub-user transactions associated with at least one of the user-selected sub-user identities.

- 5. A method comprising:
- storing, in a database, a profile keyed to a user identity and containing one or more user-selected categories to track transactions associated with said user identity, wherein individual user-selected categories include a user pre-set limit; and
- causing communication, over a communication medium and to a receiving device, of transaction summary data in the database for at least one of the one or more userselected categories, said transaction summary data containing said at least one user-selected category's user pre-set limit.
- 6. The method of claim 5, wherein the individual userselected categories further include one or more purchasable items.
- The method of claim 6 further comprising assigning individual purchasable items to one or both of: a natural category or a user-specified category.
- 8. The method of claim 5, wherein said at least one user-selected category is associated with one or more user-selected sub-user identities, and wherein said transaction summary data includes one or more sub-user transactions associated with at least one of the user-selected sub-user identities.
- 9. The method of claim 5, wherein the communication medium comprises, at least in part, a network communication medium.
- 10. The method of claim 5, wherein the communication medium comprises, at least in part, a wireless communication medium.
- 11. The method of claim 5, wherein the communication medium comprises, at least in part, a cellular communication medium
  - 12. A method comprising:
  - storing, in a database, a profile keyed to a user identity and containing one or more user-selected categories to track transactions associated with said user identity, wherein individual user-selected categories include a user pre-set limit; and
  - causing communication, over a communication medium and to a receiving device, of transaction summary data in the database for at least one of the one or more user-selected categories, said transaction summary data containing said at least one user-selected category's user pre-set limit, and wherein said transaction summary data is configured to be presented by the receiving device in
- 13. The method of claim 12, wherein the individual userselected categories further include one or more purchasable items.
- 14. The method of claim 13 further comprising assigning individual purchasable items to one or both of: a natural category or a user-specified category.
- 15. The method of claim 12, wherein said at least one user-selected category is associated with one or more user-selected sub-user identities, and wherein said transaction summary data includes one or more sub-user transactions associated with at least one of the user-selected sub-user identities.
- 16. The method of claim 12, wherein the communication medium comprises, at least in part, a network communication medium
- 17. The method of claim 12, wherein the communication medium comprises, at least in part, a wireless communication medium.

11

- 18. The method of claim 12, wherein the communication medium comprises, at least in part, a cellular communication
  - 19. A system comprising:
  - means for listing financial transactions for a user which 5 occurred during a last accounting period, said financial transactions listed in accordance with one or more userselected categories; and
  - means for presenting, in association with an individual user-selected category, an amount of the financial transactions in said individual user-selected category for said last accounting period together with a user-identified category limit associated with said individual user-selected category.
- 20. The system of claim 19 further comprising means for presenting a user profile pertaining to the financial transactions, said profile being presented using one or more of the following: the Internet, email, telephone or physically supplied information.

12

21. The system of claim 19 further comprising:

means for accepting one or more changes to at least one of the one or more user-selected categories, the one or more changes pertaining to anticipated financial transactions;

means for causing storage of said one or more changes for subsequent use.

- 22. The system of claim 19 further comprising means for listing, in association with at least one of the one or more user-selected categories, one or more sub users and their respective authorized amounts.
- 23. The system of claim 19 further comprising means for listing, in association with at least one of the one or more user-selected categories, one or more sub users and their 15 respective times of usage.
  - 24. The system of claim 19 further comprising means for allowing a user to change a natural association of items within at least one of the one or more user-selected categories.

#### (57) ABSTRACT

A computer system includes a, server having a memory connected thereto. The server is adapted to be connected to a network to permit remote storage and retrieval of data files from the memory. A file identification application is operative with the server to identify errant files stored in the memory. The file identification application provides the functions of: (1) selecting a file stored in said memory; (2) generating a unique checksum corresponding to the stored file; (3) comparing said unique checksum to each of a plurality of previously generated checksums correspond to known errant files; and (4) marking the file for deletion from the memory if the unique checksum matches one of the plurality of previously generated checksums.

#### METHOD AND APPARATUS FOR **IDENTIFYING AND CHARACTERIZING** ERRANT ELECTRONIC FILES

#### RELATED APPLICATIONS

This application is a continuation of application Ser. No. 09/561,751 filed Apr. 29, 2000, now U.S. Pat. No. 6,922,781, which claims priority pursuant to 35 U.S.C. §119(e) to U.S. Provisional Application Nos. 60/132,093, filed Apr. 30, 1999; 10 60/142,332, filed Jul. 3, 1999; and 60/157,195, filed Sep. 30, 1999. All of the foregoing non-provisional and provisional applications are specifically incorporated by reference herein, in their entirety.

#### COPYRIGHT NOTICE

This patent document contains material subject to copyright protection. The copyright owner, Ideaflood, Inc., has no objection to the reproduction of this patent document or any 20 related materials, as they appear in the files of the Patent and Trademark Office of the United States or any other country, but otherwise reserves all rights whatsoever.

#### BACKGROUND OF THE INVENTION

#### 1. Field of the Invention

The present invention relates to electronic files stored on computers, and more particularly, to methods and apparatus stored on computer storage devices.

#### 2. Description of Related Art

The use of public and shared computing environments has proliferated due to the popularity of the Internet. Many Internet service providers (ISP) offer Web hosting services at low or no cost in which registered users can place their own Web sites on the ISP's servers. These individual Web sites allow users to store and access electronic files that are uploaded to the servers. As a result of this proliferation, the administration of the large number of stored electronic files has become an 40 important aspect of such Web hosting services. In view of the relative ease of public access to these electronic file storage resources, there is also widespread abuse of Web server space in which users upload files that are offensive, illegal, unauthorized, or otherwise undesirable and thus wasteful of stor- 45 age resources. These file types are predominantly of four types: music, video, software and graphics. Many such files may contain pornography in violation of the terms of use of the Web hosting service. Moreover, the copying of these files to the Web server may be in violation of U.S. copyright laws. 50 Consequently, the identification and removal of such files represents a significant administrative burden to the Web hosting services. In addition, the presence of certain files (such as depictions of child pornography or copyrighted music files) on user computers on corporate networks poses 55 great legal risks to the corporation.

Such files can be selected for review and characterized as acceptable or unacceptable to the system administrator using an automated or manual process. Unfortunately, many undesirable files are not easily recognizable and cannot be 60 detected and characterized. A manual review of the content of the files stored on the storage resource is usually not economically feasible, and is also not entirely effective at identifying undesirable files. Illicit users of Web hosting services have devised numerous techniques for disguising improper files 65 wherein even easily recognizable file types are disguised as less recognizable file types. One such technique for disguis-

ing files is to split them into parts so that (i) they cannot be detected by simple searches for large files, and (ii) they can be downloaded or uploaded in smaller chunks so that if a transfer is interrupted, the entire download or upload is not lost. The split files may also be renamed so as to hide their true file type. For example, a search for oversized music files (\*.mp3) would not turn up a huge file named "song.txt" because it appears to the system as a text file.

Another technique for hiding files is to append them to files that legitimately belong on a web server. By way of example, a Web site may be created called "Jane's Dog's Home Page." Jane gets ten small pictures of her dog, converts them to a computer readable format (for example, jpeg) and saves them on her computer. She then splits stolen, copyrighted software 15 into ten parts. She appends each part to the end of one of the jpeg files. She then uploads these to a web server. Upon a manual review of the web page, the administrator of the site would not notice that the otherwise innocuous dog pictures actually contain stolen software, because each of the files would in fact display a photo of a dog. Thus, even if the files were reported for manual review by software doing a simple search for oversized files, the files would be left on the server because they appear to be legitimate. While these files can sometimes be identified by name or size alone, these methods 25 lead to unacceptable numbers of false positives and false negatives as file sizes and names are changed.

Free and low cost web hosting services typically rely on advertising revenue to fund their operation. An additional abuse of these web hosting services is that they can be cirfor identifying and characterizing errant electronic files 30 cumvented such that the advertisements are not displayed. Typically, the advertising content is displayed on text or hypertext pages. If a user stores graphics or other non-text files on a free web hosting server, yet creates a web page elsewhere on a different service that references these graphics or non-text files, the free web hosting service pays the storage and bandwidth costs for these files without deriving the revenue from advertisement displays.

> A need exists, therefore, to provide a method and apparatus for identifying and characterizing errant electronic files stored on computer storage devices, that makes use of a variety of file attributes to reliably characterize files according to pre-set criteria, that is not easily circumvented, and that reduces the amount of manual review necessary to verify proper operation.

# SUMMARY OF THE INVENTION

In accordance with the teachings of the present invention, a method and apparatus are provided for identifying and characterizing files electronically stored on a computer storage device. More particularly, an embodiment of the invention further comprises a computer system that includes a server having a memory connected thereto. The server is adapted to be connected to a network to permit remote storage and retrieval of data files from the memory. A file identification application is operative with the server to identify errant files stored in the memory. The file identification application provides the functions of: (1) selecting a file stored in said memory; (2) generating a unique checksum corresponding to the stored file; (3) comparing said unique checksum to each of a plurality of previously generated checksums, wherein the plurality of previously generated checksums correspond to known errant files; and (4) marking the file for deletion from the memory if the unique checksum matches one of the plurality of previously generated checksums.

A more complete understanding of the method and apparatus will be afforded to those skilled in the art, as well as a

realization of additional advantages and objects thereof, by a consideration of the following detailed description of the preferred embodiment. Reference will be made to the appended sheets of drawings that will first be described briefly.

#### BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram illustrating a wide area network in which a web host delivers information in the form of web 10 pages to users;

FIG. 2A is a flow chart illustrating a method of scanning a file directory to identify suspect files stored in a database in accordance with an embodiment of the invention;

FIG. 2B is a flow chart illustrating a method of reviewing 15 file contents to identify suspect files;

FIG. 2C is a flow chart illustrating a method of checksumming the suspect files;

FIG. 3 is a flow chart illustrating a method of generating checksum values; and

FIG. 4 is a flow chart illustrating a method of generating a checksum library.

#### DETAILED DESCRIPTION OF THE PREFERRED **EMBODIMENT**

The present invention satisfies the need for a method and apparatus for identifying and characterizing errant electronic files stored on computer storage devices, that makes use of a variety of file attributes to reliably characterize files accord- 30 ing to pre-set criteria, that is not easily circumvented, and that reduces the amount of manual review necessary to verify proper operation. In the detailed description that follows, like element numerals are used to describe like elements illustrated in one or more of the figures.

Referring first to FIG. 1, a block diagram is illustrated of a wide area network in which information is delivered to users in the form of web pages. It is anticipated that the present system operates with a plurality of computers that are coupled together on a communications network, such as the Internet 40 or a wide area network. FIG. 1 depicts a network that includes a user computer 120 that communicates with a Web host 110 though communication links that include the Internet 102. The user computer 120 may be any type of computing device that allows a user to interactively browse websites, such as a 45 personal computer (PC) that includes a Web browser application 122 executing thereon (e.g., Microsoft Internet Explorer<sup>TM</sup> or Netscape Communicator<sup>TM</sup>). The Web host 110 includes a server 112 that can selectively deliver graphical data files in the form of HyperText Markup Language 50 (HTML) documents to the user computer 120 using the HyperText Transport Protocol (HTTP). Currently, HTML 2.0 is the standard used for generating Web documents, though it should be appreciated that other coding conventions could also be used within the scope of the present invention. The 55 server 112 accesses HTML documents stored within a database 116 that can be requested, retrieved and viewed at the user computer via operation of the Web browser 122. The database 116 may also contain many other types of files, including text, graphics, music, and software files. It should 60 be appreciated that many different user computers may be communicating with the server 112 at the same time.

As generally known in the art, a user identifies a Web page that is desired to be viewed at the user computer 120 by communicating an HTTP request from the browser applica- 65 tion 122. The HTTP request includes the Uniform Resource Locator (URL) of the desired Web page, which may corre-

spond to an HTML document stored on the database 116 of the Web host 110. The HTTP request is routed to the server 112 via the Internet 102. The server 112 then retrieves the HTML document identified by the URL, and communicates the HTML document across the Internet 102 to the browser application 122. The HTML document may be communicated in the form of plural message packets as defined by standard protocols, such as the Transport Control Protocol/ Internet Protocol (TCP/IP). A user may also download any other type of file from the database 116 in the same manner.

FIG. 1 further illustrates a secondary Web host 130 having a server 132 and database 134 similar to that of the primary Web host 110. The user computer 120 can communicate with the secondary Web host 130 in the same manner as described above. Moreover, the primary Web host 110 can communicate with the secondary Web host 130 in the same manner. The pertinence of this communication path will become more clear from the following description of the present method. The Web host 110 further comprises a file identification application 114 that analyzes the data files stored on the database 116 in order to identify errant files in accordance with the present invention. The file identification application 114 may comprise a program executing on the same computer as the server 112, or may be executing on a separate computer. The file identification application tests various attributes of the files stored on the database to determine whether they satisfy a particular profile that corresponds to an errant file. Source code for a preferred embodiment of a file identification application is attached hereto as an exhibit.

A widely accepted characteristic of the Internet is that files are copied relentlessly and without permission. This is particularly true of illicit files, such as adult content, pornographic material or illegally copied software, music or graphics. Thus, a photograph showing up on a single Web site may be propagated to hundreds of other Web sites within days. Although the file name is often changed, and transmission errors often result in premature truncation of the file (and thus a new file length), the initial portion of the file remains identical as it is propagated throughout the Internet, Another characteristic of the Internet is that illicit files, such as music, video and software, all have one common attribute—they are very large once reassembled. It is therefore necessary to (i) identify oversized files that have been uploaded in parts, and (ii) identify "hidden" files that are appended to otherwise legitimate files. As will be further described below, an aspect of the present invention takes advantage of these characteristics of the Internet.

Referring now to FIGS. 2A-2C, a method for identifying and characterizing files is illustrated in accordance with an embodiment of the invention. The method would be executed by the file identification application 114 described above with respect to FIG. 1. FIG. 2A illustrates an exemplary method of scanning a file directory to identify suspect files stored in a database. Suspect files are ones that are suspected of being improper, and are marked for further testing. The database 116 includes a directory that identifies the files stored therein based on various attributes, including file name and file size. It will be appreciated from the following discussion that the method of FIGS. 2A-2C relates specifically to the identification of pornographic materials in view of the particular selection criteria that is utilized; however, it will be understood to persons of ordinary skill in the art that the selection criteria can be modified to identify other types of illicit files. Starting at step 202, the application traverses the directory in order to analyze the numerous directory entries. The application may construct a relational database of the directory entries in order to sort on the various fields of the directory. This step may be

5

performed repeatedly as a continuing process through this identifying process, and would have to be repeated periodically to identify new files that are added to the database 116.

At step 204, the application determines whether there are any sequentially numbered files within the directory. Sequen- 5 tial files can be identified by analyzing and comparing the file names to each other. One attribute of pornographic materials is that they are often uploaded to a server as part of a series of photographs. Thus, the file names may include an embedded numerical designation such as "xxx001 jpg" or 10 "xxx002.jpg". The user may define at what level of folders the software will look for sequentially numbered, lettered, or otherwise identified files. For example, if a file server is divided into folders lettered from "AA" to "ZZ", and each letters correspond to the name of the file folder, the user could decide to treat all folders on the server as a single Web site, or to treat only Web sites within the same folder as a single Web site, or to treat each Web site individually. In the preferred embodiment, each Web site is considered on its own without 20 ficking in pornographic or illicit materials. If any file names reference to other Web sites, although the invention need not be limited in this manner.

If any such sequential files are identified, they are reported as suspect files at step 206. Then, the application returns to step 202 and continues traversing through the directory 25 entries. If no sequential files are identified at step 204, the application next determines at step 208 whether there are any files having identical file sizes. Another attribute of stolen intellectual property materials such as music files is that they are often broken up into several pieces in order to thwart their 30 detection by simple searches for large files, and also to enable them to be downloaded or uploaded in smaller chunks to facilitate transfer. The presence of two or more files having identical file size within the, directory is an indicator that they may be pieces of a single, larger, illicit file. If there are plural 35 files with identical file sizes, the application determines at step 210 whether the total size of the identical files summed together would exceed a predetermined threshold. As noted above, illicit files tend to be unusually large, so the predetermined threshold would be selected to correspond with the 40 largest size of a typical non-illicit file. If the total size does exceed the predetermined threshold, then the identical files are reported as suspect files at step 206.

More particularly, the application may manipulate the file names to determine whether they are in fact likely to be parts 45 of a single, larger file. An alternative way to determine whether files should be aggregated is to delete all numbers from the file names. Any files that are identically named after the elimination of all numbers would be marked as potentially responsive and their names and aggregate size would be 50 reported. Of course, this can be limited to numbers in conjunction with specified letters (such as r00, r41, etc., as the "r" denotation often indicates file compression and division via the RAR method). Similarly, this can be limited to specified file types (whether identified by the file type suffix to the file 55 name, or by examination of the actual contents of the file) or files other than specified types (for example, legitimate graphics files such as \*.jpg are often sequentially numbered and may be a good candidate for exclusion). Next, using the original list of file names, any files are identified that differ 60 only by a user-defined number of characters. Such files would be marked as potentially responsive and their names and aggregate size would be reported. Both of the foregoing methods can be set to either ignore the file suffix or file type information or to utilize it. Next, using the original list of file 65 names and sizes, files that are of the same size (or within a user-defined number of bytes of being of the same size) are

identified. Any such files are marked as potentially responsive and their names and aggregate size would be reported.

If no identical files are identified at step 208, or if the total size does not exceed the predetermined threshold at step 210, the application proceeds to step 212 where it is determined whether the file names contain any suspect tags. An example of a suspect tag is "xxx" which is often used in association with pornographic materials. Another example of a suspect tag is "cre", which refers to a cyclical redundancy check (CRC), i.e., a known error checking technique used to ensure the accuracy of transmitting digital data. When a large file has been broken up into plural smaller files, it is common to include a CRC file in order verify the accurate reconstruction folder contains Web sites with names in which the first two 15 of the large file. The presence of a file having a "crc" tag is an indicator that an illicit or illegal file has been uploaded to the server. A table of predetermined suspect tags may be generated and periodically updated to reflect current usage within Internet newsgroups, Web sites and other facilities for trafcontaining suspect tags are identified, then the associated files are reported as suspect files at step 206.

> If no suspect tags are identified at step 212, the application proceeds to step 214 where it is determined whether the file is referenced in any HTML file contained within the directory. Ideally, the files stored on the database would each be linked to HTML files contained within the directory. Where a file is not linked to a local HTML file, this is an indicator that a user is storing graphics or other non-text files that are linked to a Web page hosted elsewhere on a different service. As described above, this situation is undesirable since the free web hosting service pays the storage and bandwidth costs for these files without deriving the revenue from advertisement displays. Accordingly, any file names that are not referenced in an HTML file contained within the directory are reported as suspect files at step 206. Alternatively, every file bearing a file type capable of causing a web browser to generate hypertext links (i.e. \*.htm, \*.html, \*.shtml, etc.) may also be reviewed. The hypertext links may be then compared against a list of illegal links (for example, links to adult-content Web sites). Any file that contains a hypertext link to such a site is reported as suspect. If all files on the directory are properly referenced in HTML files or contain no illegal links, the application determines whether the end of the directory has been reached at step 216. If the end of the directory is not yet reached, the application returns to step 202 to continue traversing the directory and identifying suspect files. Otherwise, this portion of the application ends at step 218.

Once a review of the directory entries is complete, the next step is to review the content of the files listed on the directory to see if additional files should be added to the suspect file list. This review may address every file listed on the directory not already listed on the suspect file list, or may be further narrowed using particular selection criteria specific to the type of illicit file, i.e., pornography, copyright infringement, etc. FIG. 2B illustrates an exemplary method of reviewing file contents. At step 220, the application retrieves a file from the directory. At step 222, the retrieved file is examined to identify whether the file contains a copyright notice or the symbol O. The presence of a copyright notice in the file is an indicator that the file has been uploaded to the server unlawfully, and likely contains graphics, text, software or other material that is protected by copyright. Any files containing the copyright notice would be reported as a suspect file and added to the suspect file list at step 224. This copyright notice check procedure can also be used to ensure compliance with appropri-

ate copyright laws. Alternatively, the file can be simply marked for deletion. The application then returns to step 220 and retrieves the next file.

If the file does not contain a copyright notice, the application passes to step 226, in which the retrieved file is examined 5 to determine whether the file structure is as expected for a file of the indicated type. For example, the file type "jpg" should contain a header structure with the values "255 216 255 224". Alternatively, files can be checked to ensure that they actually contain the type of data described by the file type marker (i.e., 10 a file named \*jpg should contain a jpg image). If the file does not match the indicated file type, the file can be reported as a suspect file and added to the suspect file list at step 224, or simply marked for deletion. Another alternative approach would be to replace files containing data of a type different 15 and the file marked for deletion from the database. Conthan that indicated by their file type marker by a file stating that the original file was corrupted. Yet another approach would be to retype the file (i.e. \*jpg can be retyped to \*.zip if it contained a zipped file and not a jpg). Further, certain file types can be aggregated. For example, \*.gif and \*.jpg files 20 retrieve the next file from the suspect file list. may be aggregated as a single file type, and a file bearing a .jpg type is considered valid if it contains either a gif or a jpg image. This greatly reduces the problem of mistakenly deleting a file that a consumer has innocently misnamed. The application then returns to step 220 and retrieves the next file. 25

If the file contents do match the indicated file type, the application determines at step 228 whether the file contains data extending past the end of data marker. If this marker appears before the true end of file, then it is likely that the additional data following the end of data marker constitutes a 30 portion of an illicit file. At step 230, the file is truncated at the end of file marker. The application then returns to step 220 and retrieves the next file. If the file does not contain data past the end of data marker, the application proceeds to step 232 in which it is determined whether the end of the directory has 35 been reached. If there are still additional files in the directory to review, the application returns to step 220 and retrieves the next file. If there are no additional files, the file content review process ends at step 234.

After the files within the directory have been reviewed and 40 a list of suspect files generated, the next step is to checksum the suspect files and compare the results against a library of checksum values corresponding to known illicit files. The generation of this list of known illicit files will be described below with respect to FIG. 4. FIG. 2C illustrates an exemplary 45 method of checksumming the suspect files. A checksum is a unique number based upon a range or ranges of bytes in a file. Unlike checksums as they are traditionally used in the computing field, the checksum described herein is not related to the total number of bytes used to generate the number, thus 50 reducing a traditional problem with checksums, namely that similar file lengths are more likely to generate the same checksum than are dissimilar file lengths. In a preferred embodiment of the invention, two separate checksums are generated for a file corresponding to two different length 55 portions of the file. While it is possible that the first checksum based on a shorter length portion of the file may falsely match the checksum of another file, it is highly unlikely that the second checksum would result in a false match. In addition, the use of an initial checksum based upon a small amount of 60 data, reduces the burden on the network and file server. This reduction is a result of the ability to disqualify a file that does not match the first checksum without the need to read the larger amount of data necessary to generate the second checksum.

More particularly, at step 240, the application retrieves a file from the database identified on the suspect file list. Then,

at step 242, the application reads a first portion of the suspect file. In an embodiment of the invention, the first portion comprises the first one-thousand (1,024) bytes of the file. A first checksum based on this first portion is generated at step 244. The first checksum is then compared to a library of known checksum values at step 246, and at step 248 it is determined whether there is a match between the first checksum and the library. This step provides an initial screen of a file. If there is no match, then the file likely does not correspond to a known illicit file. The file may nevertheless constitute improper or unlawful material, and it may therefore be advisable to manually review the file to evaluate its contents. If the file does contain improper or unlawful material, its checksum may be added to the library of known checksums versely, if the manual review does not reveal the file to be

improper or unlawful, or based simply on the negative result

of the first checksum comparison, the file is removed from the

suspect file list, and the application returns to step 240 to

If there is a match based on the initial screen of the file, the application proceeds to step 250 in which a second portion of the file is read. In an embodiment of the invention, the second portion comprises the first ten-thousand (10,240) bytes of the file. A second checksum based on this second portion is generated at step 252. The second checksum is then compared to a library of known checksum values at step 254, and at step 256 it is determined whether there is a match between the second checksum and the library. This step provides a more conclusive determination as to whether the file corresponds to a known improper or unlawful file. If there is a match, the file is marked for deletion (or other treatment) at step 258, and the application returns to step 240 to retrieve the next suspect file. If there is not a match, the file is removed from the suspect file list, and the application again returns to step 240 to retrieve

The files that are marked for deletion may be listed along with the pertinent information in a database (either via numerous individual files, an actual database such as SQL Server, or otherwise). This database may be manually reviewed and files that should not be deleted removed from the database. A simple file deletion program may then be run that deletes any file in the database.

the next suspect file.

As noted above, the first one-thousand bytes and the first ten-thousand bytes are used for the two checksums, respectively. For most applications, the use of the entire file or a larger portion of the file is not necessary and indeed may slow the process; however, there is no reason why the entire file or any other subset of the file could not be used. In an alternative embodiment, the first and last portions of the file are used for checksumming, although premature file truncation then becomes a way to defeat the screen. It is also possible to use other data to improve the quality of the initial screen, such as the length of the file and the file name. Any file matching the initial screen criteria is then checked against one or more checksum tests. Yet another alternative embodiment is to simultaneously generate both the initial screen checksum and the confirmation checksum in a single file read, thereby reducing the number of distinct disk access events. Verification is optional when the initial screen is performed using a checksum, as the checksum denotes a nearly certain match.

In an alternative embodiment of the invention, the present method for identifying and characterizing files can be used to block music piracy on the Internet. Each music CD carries certain identifying data that permits unique identification of that CD. MP3 encoders can be configured to encode this information into the first bytes of each MP3 file. As such, the

MP3 file would carry the signature of the music CD it was created from. This would permit a scan of all files on a server for the signature code of a particular CD. When such a code is found, it can be checked against a database of copyrighted music and any matches marked for deletion and/or review. An 5 alternative embodiment would be to prevent MP3 players from working property unless the unique identifier from a CD is found, and that unique identifier can be checked for validity against a checksum or an Internet database.

There are numerous possible algorithms that may be utilized to generate a checksum, with an exemplary algorithm shown in FIG. 3. At step 302, a single byte of the file is read. The byte is then multiplied by the current value of the checksum at step 304. On the first pass through the algorithm, a Next, at step 306, the result of the previous step is reversed (e.g., 1234 becomes 4321). At step 308, the result of the previous step is truncated to a predetermined number of digits (e.g., with the predetermined number of digits being nine, 1,234,567,890 becomes 123,456,789). At step 310, the algo-20 rithm determines whether the predetermined number of bytes has been reached. As described above, checksums are performed using the first one-thousand (1,024) and ten-thousand (10,240) bytes in accordance with a preferred embodiment of the invention. If the predetermined number of bytes has not 25 been reached, the algorithm returns to step 302 and continues with the next byte. Conversely, if the predetermined number of bytes has been reached, the algorithm ends at step 312. An advantage of this algorithm is that the checksum that is gen-This way, the likelihood of false matches is substantially reduced even though the same number of bytes are used to calculate the checksums.

It should be appreciated to persons having ordinary skill in the art the many other types of algorithms could be utilized to 35 achieve results specific to certain types of files. In an alternative embodiment of the invention, checksums of graphics files may be generated based on vector graphics analysis of the files. The graphics file may be reduced to its vector graphics components. The resulting vector graphics image is then 40 reduced to a checksum representing the vector graphics image. The checksum is then checked against a list of checksums generated in a similar matter against known or suspected inappropriate images.

An alternative method of generating a unique checksum for 45 a graphics file is by dividing an image into quadrants or other blocks and comparing the relationships between the zones into which the image is divided. For example, the relative ratio of red to green, green to blue, and blue to red in each of the zones may be calculated, and then recorded. A file could 50 then be altered in a minor way (such as by altering several bits) without defeating the ability of the software to find the

Referring now to FIG. 4, an exemplary process is illustrated for generating the library of checksum values. At step 55 402, a source of known illicit files is identified. This may be performed by manually reviewing files already stored on the database 116 of the Web host 110, such as the files identified as suspect (see FIGS. 2A-2B). Alternatively, sources of illicit files outside of the Web host 110 may be sought, such as 60 located on a secondary Web host 130. Certain Web servers may be assumed to contain files matching the criteria (i.e., a Web host that accepts adult content and runs adult oriented ads over that content will contain nearly entirely adult material). Alternatively, a target newsgroup (e.g., alt.binaries.pic- 65 tures.erotica.female) can provide a source of illicit files. Once an adequate source of files is identified, checksum values are

10

generated at step 404 in the same manner as described above with respect to FIG. 3. Then, at step 406, the checksum is stored in a library along with the file name and file length. Lastly, at step 408, it is determined whether there are other files associated with the identified source of files that can be checksummed in order to further enlarge the library. As will be further described below, the identification of a single source of illicit material will invariably lead to other sources of material. Thus, the library can be expanded at an exponen-10 tial rate. The process of FIG. 4 is repeated for each new source of illicit material. If no additional source files can be located, the process terminates at step 410.

Once a single file is located matching a predefined criteria (i.e., adult content), it is almost certain that other files also value of one is used for the current value of the checksum. 15 matching the same criteria will be found together with or in proximity to the original matching file (e.g., a Web site having one pornographic photograph will likely contain others with it). All files located with the matching file can be automatically checksummed, or can be checksummed after a manual review. Thus, the library of checksums is expanded. In view of the nature and prevalence of illicit material on the Internet, it is also likely that the matching files will also appear on other Web sites, and will thus lead to other files meeting the selection criteria that can themselves be checksummed. The expansion of the checksum library is thus exponential, and nearly the entire body of illicit materials on the Internet can be checksummed in this manner. This checksum amplification method in the automated checksumming modality can be further refined by requiring that any given checksummed file erated is independent of the number of bytes that are utilized. 30 appear together with a minimum number of other checksummed files on a minimum number of Web sites before the file represented by the checksum is considered to match the selection criteria.

It should be appreciated that one cannot defeat the present invention by simply altering an illicit image file. Although the alteration of an image file may prevent it from matching an existing checksum, the altered image will invariably be copied and posted on a new Web site together with unaltered, checksummed images, and will be inevitably checksummed using the foregoing process. Furthermore, the process can be modified so as to allow automated checksumming with a greatly reduced risk of the generation of checksums for files that do not match the selection criteria. One approach is to set a file size floor and ceiling and/or file type limitation. Another approach is to create and maintain a list of excluded files, including all publicly available "clip art" and popular mainstream advertising banners, as well as files that show up frequently on legitimate Web sites. Yet another alternative approach is to require an image to appear in proximity to known illicit files, such as files that match existing checksums, a minimum number of times before being added to the checksum library.

Furthermore, certain graphics are quite common in certain types of Web sites. For example, pornographic Web sites almost always contain a "banner" advertising membership in a commercial pornography Web site. There is a very limited universe of such banners. By generating checksums for all available pornographic banners, it is possible to locate nearly all pornographic web sites. Using the checksum amplification method described above, these advertising banner checksums would quickly lead to a very comprehensive catalog of pornographic material checksums. Similarly, illegally copied software sites often have "warez" banners. Other target file types have banners and common graphics associated with them as well.

Files matching the selection criteria can also be located by searching for hyperlinks to checksummed files or to sites

Document 1-2

11

known to contain inappropriate material. Thus, whenever a checksum is matched, the URL of the material located is recorded. Any HTML page that links to that material is then identified as likely containing material matching the selection criteria. All other graphics referenced by that HTML page 5 and/or in the same Web site may then be automatically checksummed or flagged for manual review and checksumming.

Certain key words may also be searched for on a Web site. Thus, for example, the word "fuck" in close association with "lolita" should flag a site as likely to contain child pornogra- 10 phy. This method is better used in conjunction with a manual review so as to avoid checksumming files that do not match the selection criteria, although it can also be used as an enhancement to the checksum amplification method to confirm that checksums should be automatically generated.

The results of these searches can be returned in a regular text file. Alternatively, the results may be returned in a formatted HTML file that interconnects with the file management system. The HTML file should display a copy of all files on a given Web site matching the checksum(s), all user infor- 20 mation as well as other sites using the same password, with the same user name, with the same IP address, or the same e-mail address, and the options to delete the site(s), modify the records, delete the materials, etc. Furthermore, for those file types that cannot be graphically displayed by a Web 25 browser, the "server" modality (see code attached as Exhibit) should be used to return a "file present" or "file absent" graphic to indicate whether the file is present or absent.

In an alternative embodiment of the invention, the present method for identifying and characterizing files may be imple- 30 mented in a real-time manner to review files as they are uploaded to the Web server. In yet another embodiment of the invention, the present method for identifying and characterizing files may be used to check the contents of desktop computers within a business. Thus, for example, with file and 35 access permissions set correctly, the software could determine whether pornography, child pornography, copyrighted software, or other problematic materials exist on the computers used by employees. Appropriate reporting could then be accomplished. This can also be accomplished by running the 40 software in a standalone package on desktop computers (by parents, for example). For file systems that require locally running software, the software can also be combined with necessary software (for example, the detection software could also serve as the e-mail program for the user, or as the 45 mechanism whereby the user logs into their main server).

An important advantage of the use of checksums to identify and characterize illicit files is that the customer service employees of a Web hosting company can determine with certainty that a file contains illegal contents without actually viewing the file. This is particularly important in retaining employees, as many individuals can become uncomfortable or disturbed by having to view illicit, violent or illegal images. For example, by having a library of child pornography checksums, the computer can simply report "child porn found", and 55 no employee need ever see the image. The customer service employees can then load the illegal file onto a disk to deliver to law enforcement, and terminate the customer account. Another advantage of using the checksums is that it eliminates the need for the Web hosting company to maintain 60 copies of illegal or contraband files in order to verify that files match them. Thus, it is unnecessary to keep a copy of an illegal picture or stolen music file in order to check whether files found on the server match the illicit files.

Lastly, the present method for identifying and characteriz- 65 ing files could be used to provide automatic notification to Web host customers and other interested parties. Any time a

12

file is reported as illegal, a database containing a list of customer data may be accessed to obtain the e-mail address of the site operator. An automated e-mail message may be generated (optionally copied to the Web hosting company's staff) indicating that the site has been marked for review and/or deletion. Alternatively, the fax number of the customer may be accessed and the same message sent via fax. Alternatively, the phone number may be accessed and a text-to-voice system used to send an automated telephone message. Alternatively, postal mail may be printed with the customer's address and the same message.

Having thus described a preferred embodiment of a method and apparatus for identifying and characterizing errant electronic files, it should be apparent to those skilled in 15 the art that certain advantages have been achieved. It should also be appreciated that various modifications, adaptations, and alternative embodiments thereof may be made within the scope and spirit of the present invention. The invention is further defined by the following claims.

What is claimed is:

1. A computer-implemented method for identifying and characterizing stored electronic files, said method compris-

under control of one or more configured computer systems: selecting a file from a plurality of files stored in a computer storage medium, wherein selecting the file is performed according to at least one of:

selecting the file based on the size of the file by determining whether an aggregate size of plural identically-sized files exceeds a predetermined threshold; selecting the file based on whether content of the file

matches a file type indicated by a name of the file; or selecting the file based on whether the file comprises data beyond an end of data marker for the file;

generating an identification value associated with the selected file, wherein the identification value is representative of at least a portion of the content of the selected file:

comparing the generated identification value to one or more identification values associated with one or more of a plurality of unauthorized files; and

characterizing the file as an unauthorized file if the identification value matches one of the plurality of identification values associated with the unauthorized files.

- 2. The computer-implemented method of claim 1, further comprising selecting the file from one of a plurality of sequentially-ordered files in a directory of the computer storage medium.
- 3. The computer-implemented method of claim 1, wherein generating an identification value comprises generating a checksum.
- 4. The computer-implemented method of claim 3, wherein-generating an identification value comprises generating a first checksum corresponding to a first portion of said stored file and a second checksum corresponding to a second portion of said stored file.
- 5. The computer-implemented method of claim 3, wherein generating an identification value comprises generating a first checksum corresponding to a first portion of said stored file and a second checksum corresponding to a larger portion of said stored file that includes the first portion,
- 6. The computer-implemented method of claim 1, further comprising processing a plurality of known unauthorized files to generate the plurality of identification values.
- 7. The computer-implemented method of claim 1, further comprising presenting the identified unauthorized file for human review prior to disposing of it,

13

- 8. The computer-implemented method of claim 1, further comprising automatically notifying a third party that the file has been identified.
- 9. The computer-implemented method of claim 1, further comprising deleting the identified unauthorized file from the 5 computer storage medium.
  - 10. A computer system, comprising:
  - a server having a memory connected, thereto, said server being adapted to be connected to a network to permit remote storage and retrieval of data files from the 10 memory; and
  - a file identification application operative with the server to identify unauthorized files stored in the memory, the file identification application providing the functions of:
    - selecting a file from a plurality of files stored in the 15 memory, wherein selecting the file is performed according to at least one of:
    - selecting the file by determining whether an aggregate size of plural identically-sized files exceeds a predetermined threshold;
    - selecting the file based on whether content of the file matches a file type indicated by a name of the file; or selecting the file based on whether the file comprises data beyond an end of data marker for the file;
    - generating an identification value associated with the 25 selected file, wherein the identification value is representative of at least a portion of the content of the selected file:
  - comparing the generated identification value to one or more identification values associated with one or 30 more of a plurality of unauthorized files; and
  - characterizing the file as an unauthorized file if the identification value matches one of the plurality of identification values associated with the unauthorized
- 11. The system of claim 10, wherein the application further comprises the function of selecting the file from one of a plurality of sequentially-ordered files in a directory of the computer storage medium.

14

- 12. The system of claim 10, wherein the application further comprises the function of selecting the file from a plurality of files stored in the computer storage medium, based on size of the file
- 13. The system of claim 10, wherein generating an identification value comprises generating a checksum.
- 14. The system of claim 13, wherein generating an identification value comprises generating a checksum corresponding to a first portion of the selected file and a second checksum corresponding to a second portion of the selected file.
- 15. The system of claim 13, wherein generating an identification value comprises generating a first checksum corresponding to a first portion of the selected file and a second checksum corresponding to a larger portion of the selected file that includes the first portion.
- 16. A non-transitory computer-readable storage medium having instructions stored thereon that, in response to execu-20 tion by a computing device, cause the computing device to perform a operations comprising:
  - selecting a file from a plurality of files stored in a computer storage medium, wherein selecting the file is performed according to at least one of:
    - selecting the file based on the size of the file by determining whether an aggregate size of plural identically-sized files exceeds a predetermined threshold;
  - selecting the file based on whether content of the file matches a file type indicated by a name of the file; or selecting the file based upon whether the file comprises data beyond an end of data marker for the file;
  - categorizing the selected file as an unauthorized file based on a comparison of an identification value associated with the selected file with one or more identification values associated with one or more of a plurality of unauthorized files.
